

European Landscapes and Habitats – Spatial identification and associated changes

Sander Mächer

Remote Sensing of the Environment

Thursday, January 15, 2009

Wageningen University and Research Centre (WUR), Wageningen, NL

Introduction

- Increased human pressures have caused dramatic declines in the quality and the extent of habitats across Europe.
- Habitat degradation and loss – mainly resulting from land use changes - are a primary reason of biodiversity loss.
- Therefore, there is a clear need to monitor LULC !
- These impacts are nowadays widely recognised and have forced national and international agencies to identify protected sites for natural areas with high biodiversity value.

Introduction

- Natura 2000 sites are a good example of protecting valuable sites, but it does not guarantee the preservation of biodiversity in the wider countryside.
- Therefore need to develop a Pan-European Ecological Network (PEEN) to improve the spatial coherence of remaining and fragmented habitats.
- **Spatial information about distribution European habitats is a prerequisite** for the development of a European network.

Objective

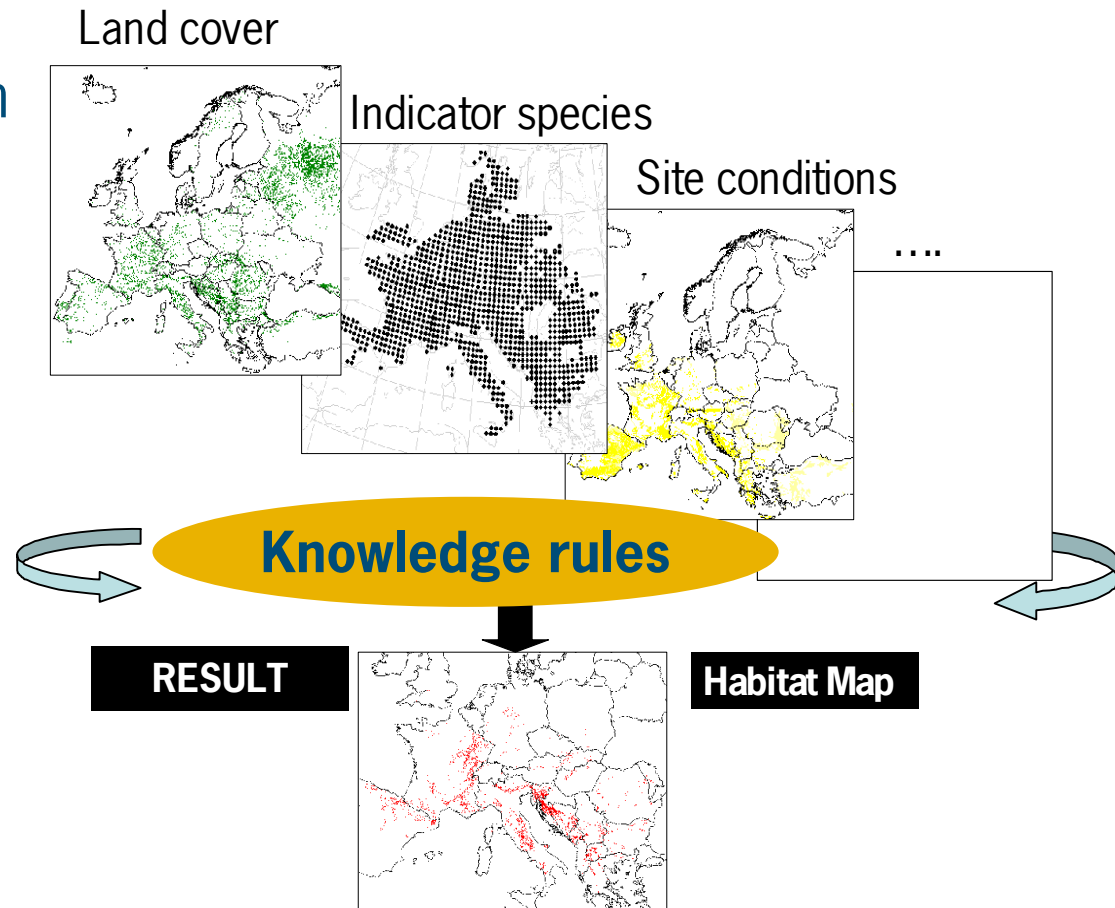

- However, **NO actual distribution maps of European habitats existed** and
- Therefore our **objective** was to **develop a methodology** for their **spatial identification** across Europe.

Methodology

The methodology should enable the spatial identification of all European habitats using state of the art European databases and decision rules on basis of:

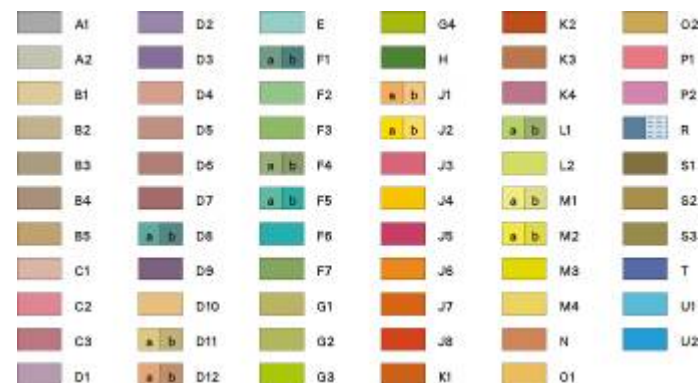

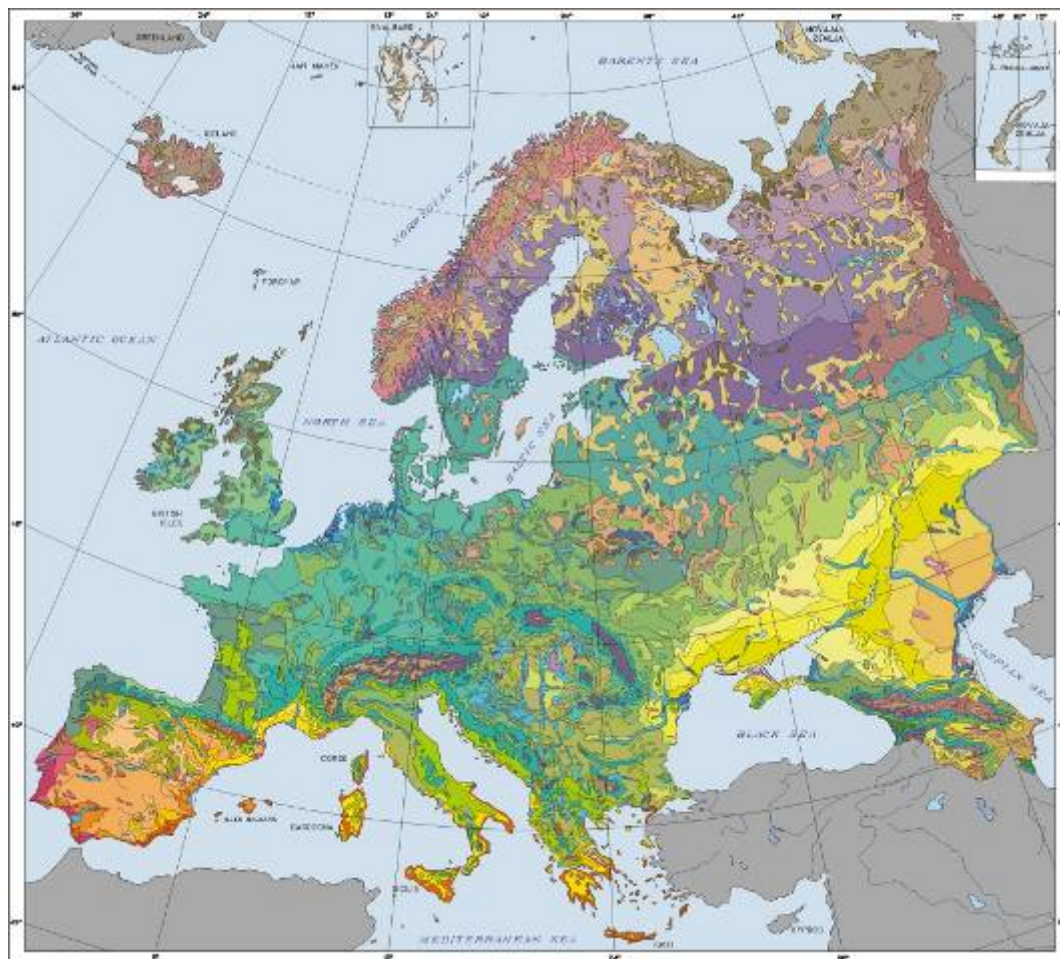

- their description in the Annex I of the Habitat Directive
- Additional expert knowledge
- Available environmental data sets

Five-step approach

- Identification, processing and integration of available core spatial data sets covering entire Europe.
- Establishment of knowledge rules for each habitat derived from the descriptions in the Annex I.
- Incorporation of additional ecological knowledge from experts, especially, where the availability of information from the Annex I was limited.
- Construction of predictive spatial distribution models.
- Validation of the results.

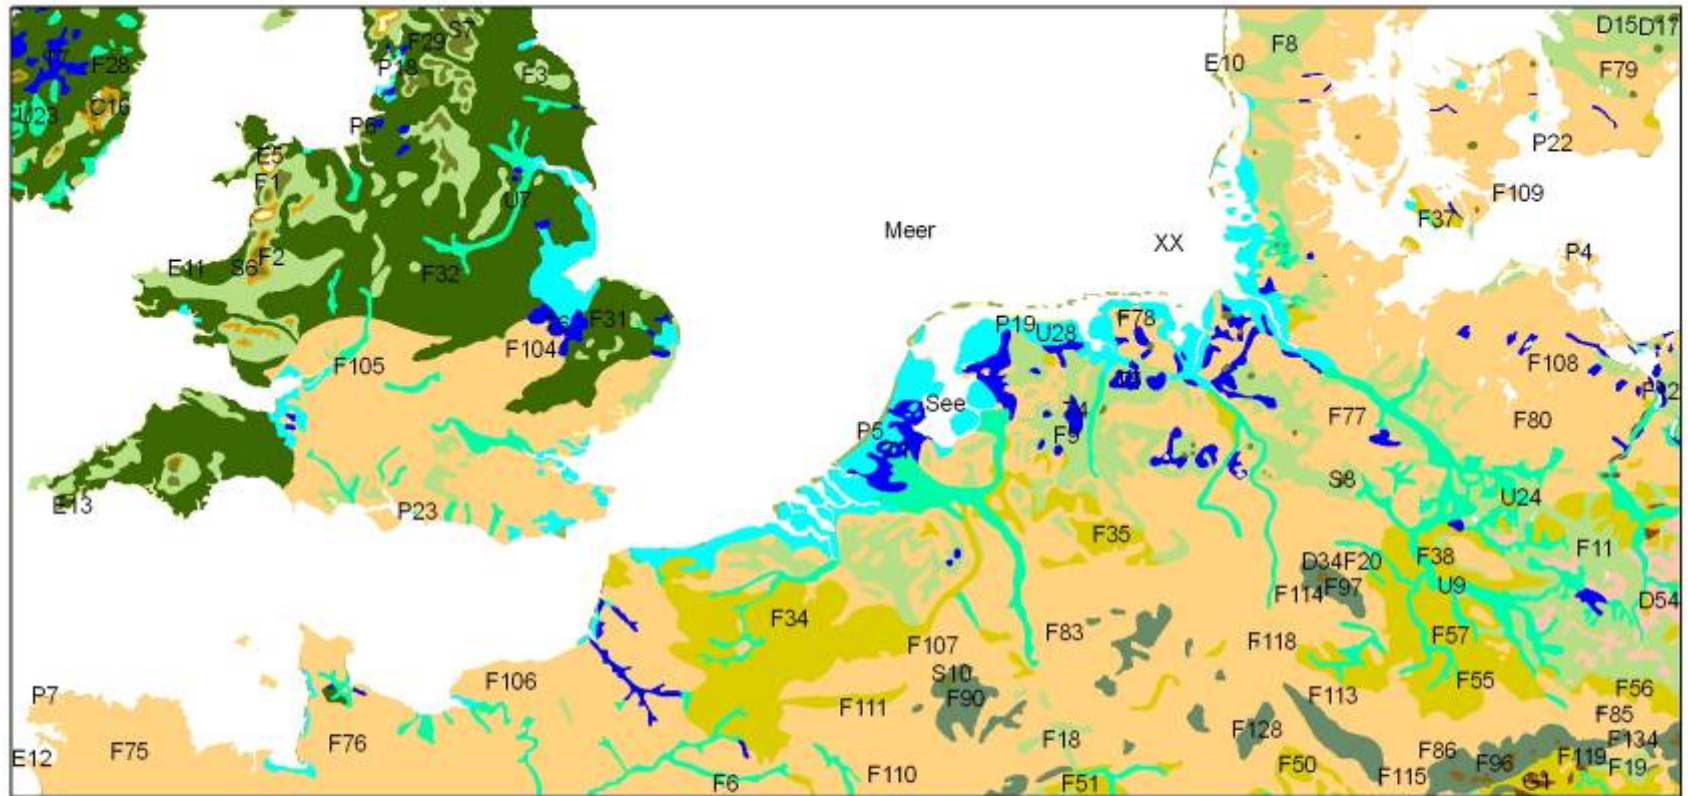

Core data: The Map of the Natural Vegetation

- Scale 1:2.5 M
- Distribution of plant communities, excluding human impact.
- Legend has 699 vegetation classes grouped in 19 main formations.
- It has a very extended database with many attributes.

Potential Natural Vegetation

- | | |
|--|---|
|  Atlantic dwarf shrub heaths |  Mixed oak-hornbeam forests |
|  Coastal and inland halophytic vegetation |  Montane to altimontane types, partly with fir and spruce |
|  Fen and swamp forests |  Montane to altimontane, partly submontane fir and spruce forests in the nemoral z |
|  Flood-plain vegetation and moist lowland forests |  Ombrotrophic mires |
|  Lowland-colline, partly submontane types (Hemiboreal spruce) |  Subcontinental thermophilous (mixed) pedunculate oak and sessile oak forests |
|  Lowland (to submontane) types (Hemiboreal and nemoral pine forests) |  Vegetation of coastal sand dunes and sea shores, often in combination with haloph |
|  Lowland to submontane types |  Vegetation of estuaries and freshwater polders |
|  Lowland to submontane types (Acidophilous oak and mixed oak forests) |  Western boreal and nemoral-montane birch forests, partly with pine fo |
|  Mixed oak-ash forests | |

Limitations of used method

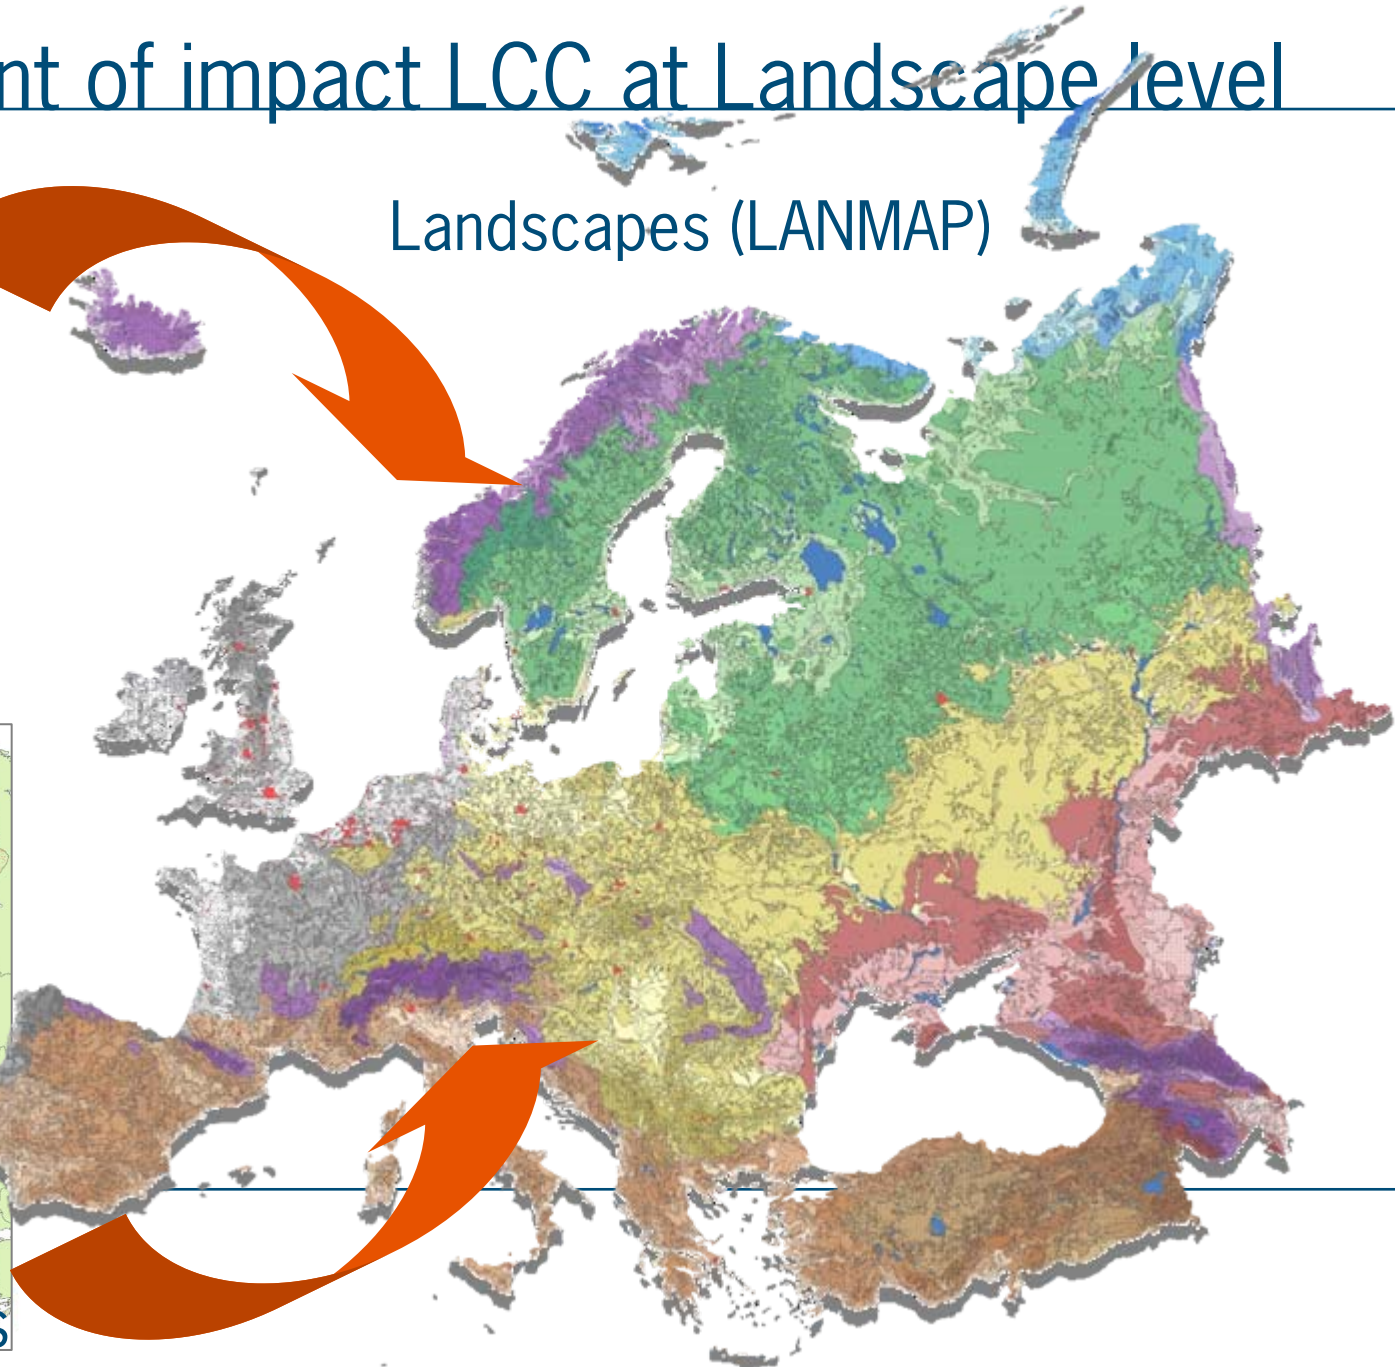

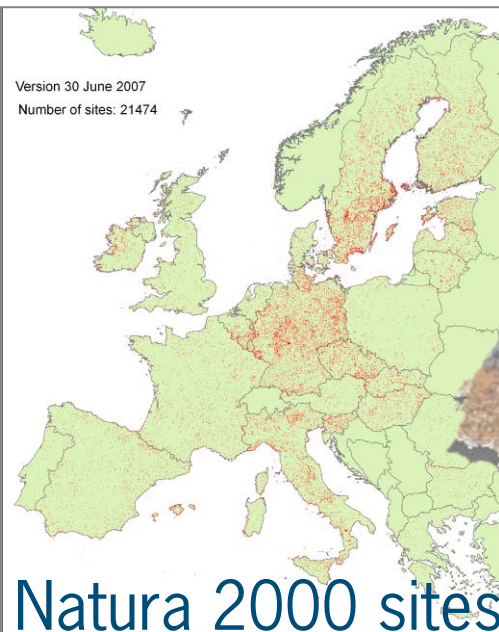

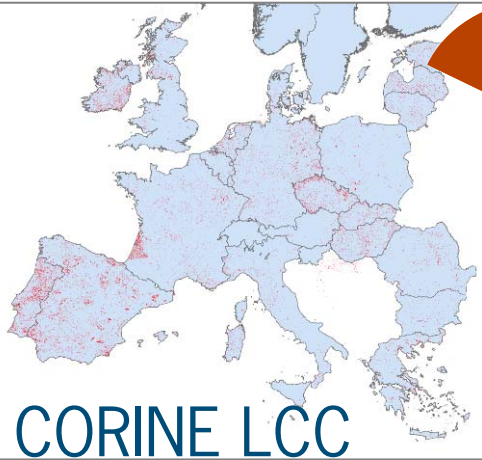

- The distribution maps involve only the likely occurrence of the habitat concerned i.e. probability.
- Over- and underestimation of the actual area due to spatial resolution.
- Therefore, we can not directly assess the surface area of the habitats.
- Alternative, is to use stratified sampling approach (e.g. BIOHAB / UK country side), but this does not provide spatial distribution of the habitats.

Opportunities of used method

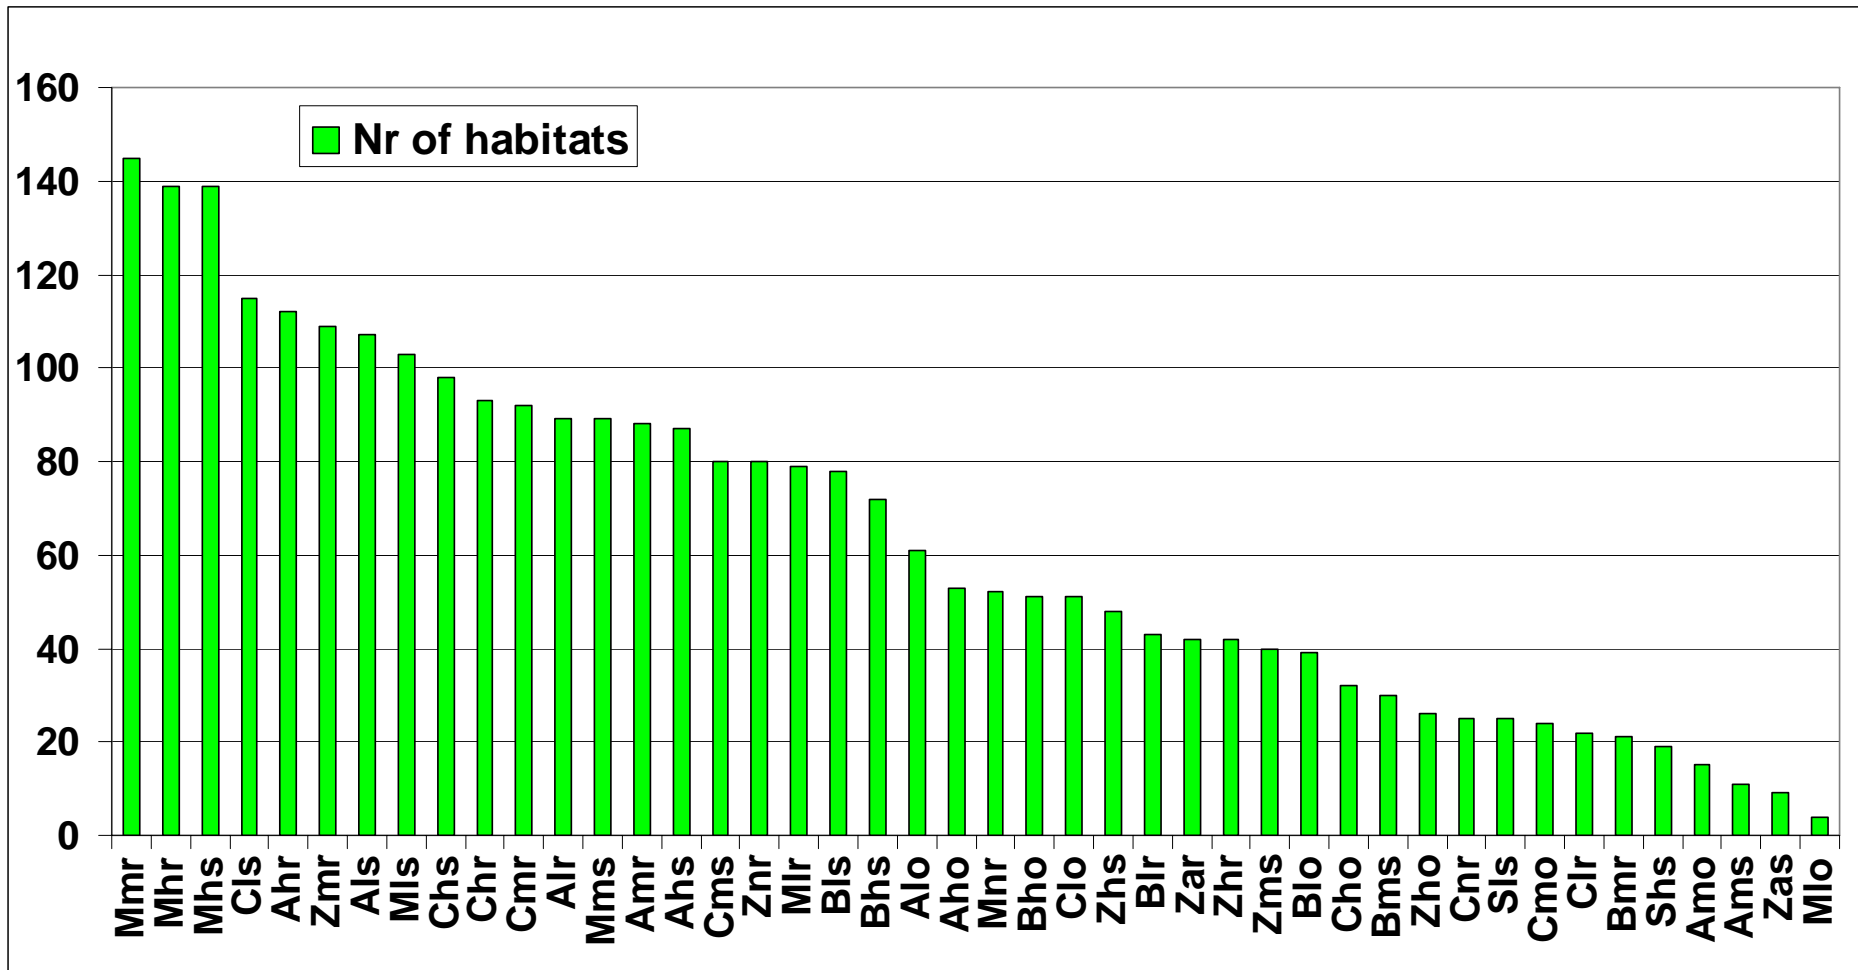

- Integration with in-situ data and survey samples to calibrate model/knowledge rules and to improve areal estimates.
- Further integration with RS derived land surface parameters (eg. FAPAR, surface albedo) and phenology.

Impact of land cover changes are site specific

- Strong variation in land cover dynamics over the different landscapes.
- Landscapes differ very much in richness of habitat types and,
- Impact on biodiversity of these land cover dynamics depends on habitat types present in the landscape and the spatial range of the habitat types affected.

Concluding

- The presented method is very useful but provides only an indication of likely occurrence.
- Uncertainties in the mapping results remain in case of poor habitat descriptions, inaccuracies or lack of environmental data sets.
- Habitats with a wider European distribution were easier to identify than local and dispersed habitats.
- Integration with vegetation relevés and survey samples needed to calibrate model/knowledge rules and to improve areal estimates.
- Further integration needed with indicators derived from Remote Sensing.
- Landscapes are suitable for analysing impact of land cover dynamics on biodiversity and shows that impacts are very site specific.

Thank you for your attention !
