# Biometris GenStat Procedure Library Manual

## 19th Edition

Edited by  
Paul W. Goedhart & Jac T.N.M. Thissen

Biometris, one of the largest groups of quantitative scientists in North-Western Europe, develops statistical and mathematical methods for the quantification of biological processes and processes in our living environment. These methods are applied and validated in practice and are often available as software packages. In addition, we provide education at the undergraduate, Master, PhD, and PostDoc levels, as well as training and consultancy for industry. We cover a wide range of application areas, from gene to ecosystem and from product to production chain. Our goal is to bring quantitative methods to life!

Biometris is the full integration of the chair groups Applied Mathematics (Molenaar) and Applied Statistics (Van Eeuwijk) with the Wageningen Plant Research business unit Biometris (Wehrens).

## Contents of the Biometris Procedure Library 19th Edition

Disclaimer and Notes ..	3	
ASNUMERIC..... converts text structures to variates .....	5	
BICORRELATE .....	forms pairwise correlations between variates including as many units as possible..... 7	
BIOMETRIS.....	accesses information, examples and source of the Biometris Procedure Library..... 9	
CHPOINTER.....	checks identifier equivalence of structures in two pointers..... 11	
CHSTRUCTURE .....	checks attributes of structures..... 13	
CNTGRANDOM.....	generates pseudo-random numbers from an (overdispersed) count distribution..... 15	
CNTPROBABILITY .....	calculates probabilities for an (overdispersed) count distribution..... 19	
COMPACT .....	compacts numerical vectors by storing unique rows .....	23
D1INTERVAL.....	plots multiple confidence intervals in a single graph.....	25
D2INTERVAL.....	plots multiple confidence intervals along with limits of concern in a single graph ....	29
D2KEYWINDOW .....	defines a keywindow inside another window.....	33
DBBILOT .....	produces a high-resolution graphical biplot.....	35
DCROP .....	crops white borders of graphic files .....	37
DIRLIST .....	provides details about (wild-carded) files in a specified directory.....	39
DORDINAL .....	plots and displays the results of a simple ordinal logistic regression model .....	41
EDCONTINUOUS .....	calculates equivalent deviates for continuous distributions.....	45
EMMULTINORMAL.....	estimates parameters of the multivariate normal for data with missing values .....	47
FDERIVATIVE .....	calculates numerical derivatives of a function .....	49
FEXPAND .....	forms a variate/factor by expanding a structure a specified number of times .....	53
FGRID.....	forms a grid of values in one or more dimensions .....	55
FINTEGRATE.....	calculates a definite integral of a function of one argument.....	57
FISHEREXACT .....	performs pairwise tests of independence of rows in a r x 2 table.....	59
FMINIMIZE.....	minimizes a function of one argument by (modified) golden section search.....	61
FPOINTER .....	forms a pointer from a text structure.....	65
FPRODUCT .....	forms a factor with a label for every combination of other factors .....	67
FROOTFIND.....	finds the root of a function of one argument by (modified) bisection .....	69
FSUBFACTOR.....	forms a factor to index the units within another factor .....	73
FUNIQUETEXT .....	forms a text with unique strings from another text .....	75
GAUSSPOINTS .....	calculates nodes and weights for Gauss-Hermite and Gauss-Legendre integration ...	77
GENBATCH .....	runs several GenStat programs simultaneously in batch .....	79
GMULTIVARIATE.....	generates random numbers from multivariate normal or Student's t distribution.....	83
GRUBBSTEST.....	Performs Grubbs' test for a single outlier.....	85
GUNITCUBE.....	generates random numbers from a distribution with marginal uniform distributions.	87
IRCLASS .....	fits a generalized linear mixed model to grouped response variables.....	89
IRREML.....	fits a generalized linear mixed model .....	93
LRPAIR.....	gives likelihood ratio tests for all pairwise differences from a regression or GLM....	97
MATCHTARGET .....	extracts units of a set of vectors by matching a target vector .....	99
MOSTSIMILAR .....	displays the most similar units for each candidate unit given a set of variates.....	101
OCATTRIBUTES .....	calculates OC curves for acceptance sampling plans for attributes .....	103
OCPLAN.....	finds an acceptance sampling plan for attributes given two points on an OC curve.	105
PER2MUTE .....	forms all possible permutations of a set of values.....	107
PPAIR .....	displays results of t-tests for pairwise differences in compact diagrams .....	109
QDIRECTORY.....	returns a directory selected by means of a directory browse dialog box on screen ..	113
QENQUIRE .....	provides details about files and can be used to open or close files .....	115
QFILENAME.....	returns filename(s) selected by means of a file open dialog box on screen.....	117
QMESSAGE .....	displays a message on screen.....	119
QPICKLIST.....	can be used to pick one or more items from a list presented on screen .....	121

Continue on next page

## Contents continued

QREGISTRY .....	can be used to retrieve registry keys from the registry .....	123
QSTOPWATCH.....	can be used to display timing information .....	125
QTEXT .....	can be used to obtain string(s) of a text structure from screen .....	127
QTIMEDELAY.....	pauses execution for a specific amount of time.....	129
QYESNO .....	can be used to choose between alternatives Yes, No and Cancel on screen.....	131
R2NEGBINOMIAL.....	fits a negative binomial GLM estimating the aggregation parameter .....	133
RBETABINOMIAL.....	fits the beta-binomial regression model to overdispersed proportions.....	137
RCENSORED .....	fits a censored regression model with normal errors.....	141
RENAMEPOINTER.....	renames the structures of a pointer .....	145
RGDISPLAY .....	displays and stores the non-groups parameters of a within-groups regression.....	147
RLMS.....	does regression by least median squares .....	149
RLOGITNORMAL .....	fits the Logit-Normal regression model to overdispersed proportions.....	153
RMLSTACK .....	“stacks” data to allow the fitting of a multinomial logistic regression model .....	157
RMLUNSTACK.....	“unstacks” results of a multinomial logistic regression model.....	159
RPLOGNORMAL.....	fits the Poisson-Lognormal regression model to overdispersed counts .....	161
RPLS.....	does regression by partial least squares with leave-out options.....	165
RSELECT.....	selects best subsets of predictor variables in regression.....	169
RUNCERTAINTY .....	calculates contributions of model inputs to the variance of a model output.....	173
SETDEVICE .....	opens a graphical file on the basis of a file extension .....	175
SFILENAME .....	splits a filename, which is opened by GenStat or not, into substrings .....	179
SPECIALFUNCTION .....	calculates a number of special mathematical functions .....	181
SREPLACE .....	replaces (or removes) substrings from each string of a text structure .....	183
SUMMARIZE .....	prints summary statistics for variates .....	185
SYM2VARIATE.....	copies a symmetric matrix to a variate along with row and column information.....	187
TPOWER .....	calculates and plots the power of Student’s difference and equivalence t-tests .....	189
TSQUEEZE .....	squeezes a table to fewer levels of the classifying factors .....	193
V2TABLE.....	forms a variate and a set of classifying factors from a table .....	195
VSEARCH.....	helps search through models for a generalized linear mixed model (GLMM).....	197
VWALD .....	saves non-hierarchical Wald tests for fixed terms in a REML analysis .....	201
WEAVEVECTORS .....	weaves two sets of vectors into a new set according to the first vector of both sets .....	203

## Disclaimer for the Biometris Procedure Library 19th Edition

Permission to use, copy and distribute the Biometris GenStat Procedure Library and its documentation for any purpose is hereby granted without fee, provided that the entire package is kept together and that this permission and disclaimer notice appears in all copies.

Biometris, Wageningen Plant Research (WPR) and Wageningen University and Research (WUR) make no warranty of any kind, expressed or implied, including without limitation any warranties of merchantability and/or fitness for a particular purpose. Biometris, WPR and WUR do not assume any liability for the use of this software. In no event will Biometris, WPR or WUR be liable to you for any additional damages, including any lost profits, lost savings, or other incidental or consequential damages arising from the use of, or inability to use, this software and its accompanying documentation, even if Biometris, WPR or WUR has been advised of the possibility of such damages.

## Notes for the 19th Edition

- The Biometris GenStat Procedure Library and the library manual can be downloaded from the internet address <http://www.wageningenur.nl/en/show/GenStat-Procedures.htm>. Just run the installation program to install the library. The Library contains a collection of procedures mainly written by members of [Biometris of Wageningen University and Research](#).
- A procedure can be cited as follows: Goedhart, P.W. (2018). Procedure VSEARCH. In: Biometris GenStat Procedure Library Manual 19th Edition (Editors: Goedhart, P.W. and Thissen, J.T.N.M). Biometris report 40.05.18, Biometris, Wageningen.
- The following procedures are new in this edition: ASNUMERIC, D2KEYWINDOW, D1INTERVAL, D2INTERVAL and GRUBBSTEST. Procedure DDEVICE has been removed.
- Procedures DCROP, DIRLIST, GENBATCH, PER2MUTE, QDIRECTORY, QENQUIRE, QFILENAME, QMESSAGE, QPICKLIST, QREGISTRY, QSTOPWATCH, QTEXT, QTIMEDELAY, QYESNO, RLMS, RPLS, RSELECT and TPOWER employ an external C# program, using .NET Framework 3.5. The external program is called by means of the SUSPEND directive. You can check whether the correct .NET Framework is installed by running the example program of the QMESSAGE procedure. This should display a message box on screen.
- The BIOMETRIS [PRINT=allfiles] command outputs the example and source code of all the Biometris procedures in a directory named "BiometrisSource" below the current working directory.
- Uncertainty and regression-based sensitivity analysis of a deterministic model can be performed using Biometris procedures EDCONTINUOUS, GMULTIVARIATE, GUNITCUBE and RUNCERTAINTY. Biometris report 11.12.05 describes these procedures in detail and includes a number of illustrative examples. This report is distributed with this library and can be found in the Biometris subdirectory below the AddIns folder of GenStat.
- Procedures PPAIR and SETDEVICE succeed a procedure in the official GenStat Procedure Library and have some new options and/or parameters. Options SPACES and NOMESSAGE have been added to PPAIR in this release.

# ASNUMERIC

P.W. Goedhart

Converts text structures to variates

[contents](#) - [next](#)

## Options

PRINT = <i>string token</i>	What to print (nonnumeric). default nonnumeric prints the non-numeric values in the text structures
CONTINUE = <i>string token</i>	Whether to continue when non-numerical values are encountered in the text structures (no, yes); default no generates a fatal fault
KEEPVALUES = <i>string token</i>	Whether to keep numerical values when non-numerical values are present in a text structure (no, yes); default no sets all the elements of the corresponding variate to missing, yes only sets the non-numerical values to missing
REDEFINE = <i>string token</i>	Whether to allow a text in the TEXTS list to be redefined as a variate (yes, no); default no
MISSING = <i>text</i>	Strings that are converted to missing values; default *
NOMESSAGE = <i>string token</i>	Which warning messages to suppress (warnings) default *

## Parameters

TEXTS = <i>texts</i>	Text structures that are converted to variates
VARIATES = <i>variates</i>	Variates to receive the numerical values of the text structures; default * will, if REDEFINE=yes, cause the corresponding TEXTS itself to be defined as variates
SAVESET = <i>variates</i>	List of the units with non-numerical values in the text structures
NULL = <i>scalars</i>	Indicator for each text structure, set to 1 when all the values are numerical or 0 otherwise

## Description

Procedure ASNUMERIC converts text structures to variates. The texts are specified by the TEXTS parameters while the variates that will receive the values are specified by the VARIATES parameter. You can redefine a TEXTS structure as a variate by setting option REDEFINE=yes and omitting to specify any corresponding identifier in the VARIATES list. The SAVESET parameter can be used to save the numbers of the units with non-numerical values. The NULL parameter can specify a list of scalars, one for each text in the TEXTS list, that will be set to one if all the values are numerical; otherwise it is set to zero. The PRINT option defines whether all the non-numerical values are printed. Warnings messages can be circumvented by specifying the NOMESSAGE option.

In case non-numerical values are encountered, a fatal fault will be produced. This can be circumvented by setting option CONTINUE=yes. In that case option KEEPVALUES determines how text structures with non-numerical values are converted. By default, i.e. KEEPVALUES=no, all the elements of the associated variate are set to missing. Setting KEEPVALUES=yes will only set the non-numerical values to missing. Note that spaces in the middle of strings and colons are not allowed; these will also produce a fatal fault.

The MISSING option can be used to specify strings that are converted to (numerical) missing values. Note that empty lines, missing values in the text structure, and the string '\*' are all converted to missing values. Also note that before conversion leading and trailing spaces in the text structure are skipped.

## Method

The CONCATENATE directive is used to skip all leading and trailing spaces in the TEXTS structures, and subsequently strings in MISSING (also after skipping leading and trailing spaces) are replaced by '\*'. The resulting text structure is written to a temporary file, and the associated variate is read from that file. Errors while reading the temporary file are outputted to a second temporary file from which it is inferred whether any errors, i.e. non-numerical values, occurred while reading.

**Action with RESTRICT**

The TEXTS identifiers and the MISSING identifier should not be restricted.

**References**

**Example**

```

CAPTION 'ASNUMERIC example 1: REDEFINE=yes' ; STYLE=meta
TEXT [VALUES=100000('10')] long1
TEXT [VALUES=100000('20')] long2
ASNUMERIC [REDEFINE=yes] long1,long2
PRINT MEAN(long1,long2)
CAPTION ' ASNUMERIC example 2: non-numerical and missing values' ; STYLE=meta
TEXT t1 ; !t('11 ', ' ', *, '*', 'XXXX', '28', ' ', ' ', 'YYYY', ' 10')
TEXT t2 ; !t('41', ' ', '12', 'ZZZZ', '100')
TEXT t3 ; !t('73','6','98', '1.2e2', '80.0E-1')
ASNUMERIC [CONTINUE=yes] t1,t2,t3 ; v1,v2,v3
PRINT t1,v1,t2,v2,t3,v3 ; FIELD=12,6 ; DECI=0
ASNUMERIC [CONTINUE=yes ; KEEPVALUES=yes] t1,t2,t3 ; v1,v2,v3
PRINT t1,v1,t2,v2,t3,v3 ; FIELD=12,6 ; DECI=0
ASNUMERIC [CONTINUE=yes ; MISSING=!t(XXXX,YYYY,ZZZZ)] t1,t2,t3 ; v1,v2,v3
PRINT t1,v1,t2,v2,t3,v3 ; FIELD=12,6 ; DECI=0
ASNUMERIC t1,t2,t3 ; v1,v2,v3

```

## BICORRELATE

J.T.N.M. Thissen

Forms pairwise correlations between variates including as many units as possible

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What to print (correlations, nobservations, tests); default correlations
METHOD = <i>string token</i>	Type of test to make (against zero) for the correlations (twosided, greaterthan, lessthan); default twosided
CORRELATIONS = <i>symmetric matrix</i>	Stores the pairwise correlations between the variates specified by the VARIATES parameter
PROBABILITIES = <i>symmetric matrix</i>	Saves the test probabilities
NOBSERVATIONS = <i>symmetric matrix</i>	Stores the pairwise number of observations on which the correlations are based

### Parameters

VARIATES = *variates*                      Variates for which the correlations are to be calculated; must be set

### Description

Procedure BICORRELATE calculates pairwise correlations by excluding only units with missing values in the corresponding pair of variates. Note that the CORRELATE directive and procedure FCORRELATION exclude all units with at least one missing value in the set of variates. Printed output is controlled by the PRINT option with settings:

correlations    prints the correlation matrix;  
tests            prints tests for the correlations.

By default PRINT=correlation. The METHOD option indicates the type of test to be done, with settings:

twosided        for a two-sided test of the null hypothesis that the correlation is zero;  
greaterthan    for a one-sided test of the null hypothesis that the correlation is not greater than zero;  
lessthan        for a one-sided test of the null hypothesis that the correlation is not less than zero.

Tests cannot be produced if there are fewer than two observations. The correlation matrix can be saved using the CORRELATIONS option, the (symmetric) matrix of test probabilities can be saved using the PROBABILITIES option, and the number of observations upon which it is based can be saved using the NOBSERVATIONS option.

### Method

BICORRELATE uses the CORRELATION function for each pair of variates.

### Action with RESTRICT

The VARIATES identifiers may be restricted. If they are restricted they must be restricted in the same way

### References

None.

### Procedures Used

None.

### Similar Procedures

FCORRELATION forms the correlation matrix for a list of variates.

# BIOMETRIS

P.W. Goedhart

Accesses information, examples and source of the Biometris Procedure Library

[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string tokens</i>	Printed output required ( <i>information</i> , <i>allfiles</i> ); default *, i.e. no printing, or <i>information</i> when no other options or parameters have been set
CONTENTS = <i>text</i>	Saves the contents of the Biometris Procedure Library
LIBRARYFILE = <i>text</i>	Saves the full filename of the Biometris Procedure Library
EXAMPLESFILE = <i>text</i>	Saves the full filename of the backingstore file in which the example and source code of all Biometris procedures is stored
DOTNETPROGRAM = <i>text</i>	Saves the full filename of the external C# program used by procedures which employ the SUSPEND mechanism
DEVICE = <i>scalar</i>	Saves the default device used by the DDEVICE procedure; default 4 for the Windows implementation
EXIT = <i>scalar</i>	Saves a scalar which is used internally by other Biometris procedures
GENDIRECTORY = <i>text</i>	Saves the main GenStat directory
VERSION = <i>text</i>	Saves version information of the Biometris Procedure Library

## Parameters

PROCEDURE = <i>texts</i>	Single-valued texts indicating the procedures about which the information is required
EXAMPLE = <i>texts</i>	To store the example for each procedure
SOURCE = <i>texts</i>	To store the source code for each procedure
DATA = <i>texts</i>	To store example data, if applicable, for each procedure

## Description

Procedure BIOMETRIS allows you to obtain an example of the use of any procedure in the Biometris Procedure Library, also to access the source code of any procedure, so that you can see how it works, or modify it. For procedures which employ the PASS mechanism, Fortran code of subroutines is also available. The names of procedures for which examples and source code are required should be listed, in quotes, using the PROCEDURE parameter. The EXAMPLE parameter can be used to specify the identifier of a text to store each example and the SOURCE parameter to store the source code. The DATA parameter stores example data used in the example program for some procedures. The following code would run an example of the RSELECT procedure.

```
BIOMETRIS 'RSELECT' ; EXAMPLE=ExRselect
EXECUTE    ExRselect
```

The PRINT=*information* setting prints a list of index lines giving brief details about the Biometris procedures. It also prints the full name of all the files which are relevant for the Biometris Procedure Library: (1) the Procedure Library file, (2) the backingstore file with the examples and source code and (3) the full filename of the C# program used by procedures which employ the SUSPEND mechanism. These can also be stored by setting options LIBRARYFILE, EXAMPLESFILE and DOTNETPROGRAM respectively. The GENDIRECTORY option saves the main GenStat directory. The VERSION option saves the current edition of the Biometris Procedure Library and the release date.

The PRINT=*allfiles* setting outputs the example, source code and associated Fortran code of all Biometris procedures in a directory named "BiometrisSource" below the current working directory.

The CONTENTS option can be used to save the contents of the Biometris Procedure Library. The DEVICE option saves the default device which is used by the DDEVICE procedure. The default value is 4. Its main use is in the DDEVICE procedure. The EXIT option saves a scalar which is used internally by other Biometris procedures.

## Method

The examples, source code and example data are held in a backing-store file. These are accessed using standard retrieval of text structures.

## Action with RESTRICT

Not relevant.

## References

None.

## Procedures Used

None.

## Similar Procedures

LIBEXAMPLE accesses examples and source code of library procedures in the GenStat Procedure Library.

## Example

```
CAPTION 'BIOMETRIS example' ; STYLE=meta
BIOMETRIS [PRINT=information]
BIOMETRIS 'RSELECT' ; EXAMPLE=ExRselect
PRINT ExRselect ; FIELDWIDTH=1 ; JUSTIFICATION=left ; SKIP=0
EXECUTE ExRselect
```

## CHPOINTER

*L.C.P. Keizer & J.T.N.M. Thissen*

Checks identifier equivalence of structures in two pointers

[contents](#) [previous](#) [next](#)

### Options

PRINT = *string token*

What to print (information); default \*

CASE = *string token*

Whether lower- and upper-case (small and capital) letters are to be regarded as identical in identifiers (significant, ignored); default significant

### Parameters

CHECKPOINTER = *pointers*

Pointer whose structures are checked ; must be set

TARGETPOINTER = *pointers*

Pointer whose structures are compared with the structures in CHECKPOINTER; must be set

PRESENT = *variates*

Saves a variate of the same length as the CHECKPOINTER parameter with elements 1 (structure present in TARGETPOINTER) or 0 (structure absent in TARGETPOINTER)

ALLPRESENT = *scalars*

Scalar to save whether all structures of CHECKPOINTER are present in TARGETPOINTER (1) or at least one structure is absent (0)

### Description

Procedure CHPOINTER can be used to check whether structures of the CHECKPOINTER parameter are present in the TARGETPOINTER parameter or not. Note that only the first 32 characters of an identifier are relevant. The CASE option specifies whether the case of letters (small and capital) in the identifiers of CHECKPOINTER and TARGETPOINTER should be regarded as significant or ignored when comparing the identifiers. The PRESENT parameter can be used to save a variate of the same length as the CHECKPOINTER parameter with elements 1 and 0, indicating whether the corresponding structure of CHECKPOINTER is present (1) in TARGETPOINTER or absent (0). The ALLPRESENT parameter saves whether all structures of CHECKPOINTER are present in TARGETPOINTER (1) or at least one structure is absent (0).

PRINT=information prints presence of the structures and a warning when structures differ only in lower- and upper-case of their letters.

### Method

CHPOINTER uses standard GenStat directives for data manipulation.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

None.

### Similar Procedures

None.

**Example**

```
CAPTION 'CHPOINTER example' ; STYLE=meta
POINTER [VALUES=AA,b,C,d] check
POINTER [VALUES=aa,e] target
CHPOINTER [PRINT=information ; CASE=ignored] CHECKPOINTER=check ; \
TARGETPOINTER=target
POINTER [VALUES=AA,aa] case
CHPOINTER CHECKPOINTER=case ; TARGETPOINTER=target ; PRESENT=present
PRINT case, present
```

## CHSTRUCTURE

J.T.N.M. Thissen &amp; L.C.P. Keizer

Checks attributes of structures

[contents](#) [previous](#) [next](#)

### Options

PRINT = *string token*

What to print (information); default \*

### Parameters

STRUCTURES = *pointers*

Pointer to structures to check; must be set

TYPE = *texts*

Saves a text of the same length as the STRUCTURES parameter with the type of the structures

DECLARED = *variates*

Saves a variate of the same length as the STRUCTURES parameter with elements 1 if the structure is declared or 0 if the structure is not declared

ALLDECLARED = *scalars*

Scalar to save whether all the elements of the STRUCTURES parameter are declared (1) or at least one structure is not declared (0)

PRESENT = *variates*

Saves a variate of the same length as the STRUCTURES parameter with elements 1 if the structure has values or 0 if the structure has no values

ALLPRESENT = *scalars*

Scalar to save whether all the elements of the STRUCTURES parameter have values (1) or at least one structure has no values (0)

NVALUES = *variates*

Saves a variate of the same length as the STRUCTURES parameter with the number of values of the structures

NMV = *variates*

Saves a variate of the same length as the STRUCTURES parameter with the number of missing values of the structures

### Description

Procedure CHSTRUCTURE can be used to check structures with respect to declaration, presence of values and the number of (missing) values. The STRUCTURES parameter defines the identifiers to check. The TYPE, DECLARED, PRESENT, NVALUES and NMV parameters all have the same length as the STRUCTURES pointer. The TYPE text saves an asterisk (\*) for non-declared identifiers. The DECLARED parameter saves a 1 for declared structures and a 0 otherwise. The PRESENT parameter saves a 1 for structures with (possibly missing) values and a 0 otherwise. The parameters NVALUES and NMV save the number of values and the number of missing values respectively. The ALLDECLARED parameter saves whether all structures of the STRUCTURES parameter are declared (1) or at least one is not (0), whereas the ALLPRESENT parameter saves whether all structures of the STRUCTURES parameter have values (1) or at least one has not (0).

The option setting PRINT=information prints an overview of the different attributes of the structures.

### Method

CHSTRUCTURE uses standard GenStat directives for data manipulation.

### Action with RESTRICT

Restrictions on structures in the STRUCTURES pointer are ignored, i.e. the number of (missing) values is calculated for unrestricted vectors.

### References

None.

### Procedures Used

None.

## Similar Procedures

None.

## Example

```
CAPTION      'CHSTRUCTURE example' ; STYLE=meta
SCALAR       scal
VARIATE      [NVALUES=10] vari1
VARIATE      [VALUES=5(*)] vari2
VARIATE      [VALUES=1...3] vari3
TEXT         text
SYMMETRIC    [ROWS=10] symm
POINTER      [VALUES=scal, vari1, vari2, vari3, text, symm, not1, not2] input
CHSTRUCTURE [PRINT=information] input ; TYPE=type ; DECLARED=declared
PRINT        input, type, declared
```

# CNTGRANDOM

P.W. Goedhart

Generates pseudo-random numbers from an (overdispersed) count distribution

[contents](#) [previous](#) [next](#)

## Options

DISTRIBUTION = <i>string token</i>	Distribution for which pseudo-random numbers must be generated (poisson, opoisson, negativebinomial, plognormal, power, binomial, betabinomial, blogitnormal); default poisson
LINK = <i>string token</i>	Link function for binomial-logit-normal distribution (logit, probit, complementaryloglog); default logit
POWER = <i>scalar</i>	Power in variance-to-mean relationship for the power distribution; default 1.5
SEED = <i>scalar</i>	Seed to generate the random numbers; default 0 continues an existing sequence or initialises the sequence automatically if no random numbers have been generated in this job

## Parameters

MEAN = <i>variates</i>	Poisson mean $\mu$ or binomial probability $\pi$ of the count distribution; must be set
NBINOMIAL = <i>scalars</i> or <i>variates</i>	Number of binomial trials; must be set for a binomial type distribution
DISPERSION = <i>scalars</i> or <i>variates</i>	Dispersion parameter of overdispersed count distribution; must be set for an overdispersed distribution
NUMBERS = <i>variates</i>	Saves the random numbers from the distribution

## Description

CNTGRANDOM can be used to generate random numbers from an (overdispersed) count distribution. The distribution can be either of the Poisson type (poisson, opoisson, negativebinomial, plognormal, power) or the binomial type (binomial, betabinomial, blogitnormal), and this is set by the DISTRIBUTION option. For the Poisson type distributions the MEAN parameter specifies the mean  $\mu$  of the distribution. For the binomial type distributions the MEAN parameter specifies the probability  $\pi$  of the distribution, and the NBINOMIAL parameter must be set to specify the number of binomial trials. The DISPERSION parameter must be set for overdispersed Poisson or overdispersed binomial distributions which are defined below.

1. The overdispersed Poisson distribution (opoisson) can be obtained by mixing the Poisson distribution with the gamma distribution. This distribution assumes that the Poisson mean itself follows a gamma distribution with mean  $\mu$  and index parameter  $v\mu$  (McCullagh and Nelder, 1989). This results in what is called here the overdispersed Poisson distribution which has mean  $\mu$  and variance  $\mu(1+v)/v$ . This distribution thus has a variance which is proportional to the mean. The DISPERSION parameter specifies the parameter  $\phi = (1+v)/v$  which must be larger than 1.
2. The negative binomial distribution (negativebinomial) is also obtained by mixing the Poisson with the gamma, but now employing a gamma index parameter  $1/v$ . This results in the negative binomial distribution which has mean  $\mu$  and variance  $\mu+v\mu^2$ . The DISPERSION parameter specifies the parameter  $v$  which must be positive.
3. The Poisson-lognormal distribution (plognormal) is related to a generalized linear mixed model. In this case the logarithm of the mean of the Poisson distribution is generated by a normal distribution with mean  $\lambda$  and variance parameter  $\sigma^2$ . Using  $\sigma^2 = \text{Log}(v+1)$  and  $\lambda = \text{Log}(\mu) - \sigma^2/2$  results in a distribution with the same mean  $\mu$  and variance  $\mu+v\mu^2$  as the negative binomial distribution. Note that probabilities and other moments are not the same. The DISPERSION parameter specifies the parameter  $v$  which must be positive. The MEAN parameter specifies  $\mu$  rather than  $\lambda$ .
4. Taylor (1961) proposed the power relationship  $V = \sigma^2\mu^p$  between the variance  $V$  and the mean  $\mu$  for field population counts, and this is sometimes termed Taylor's Power law. There is no

statistical distribution associated with Taylor's power law, as it only specifies a relationship between the variance and the mean. Perry et al (2003) used the negative binomial distribution to simulate according to Taylor's power law by solving  $v$  from  $\sigma^2 \mu^p = \mu + v\mu^2$  and this approach is also followed here. Note that using the negative binomial is arbitrary, as e.g. the Poisson-Lognormal has the same variance to mean relationship, but has a different distribution. The `DISPERSION` parameter specifies the parameter  $\sigma^2$  which must be positive and the `POWER` option specifies the power  $p$  in the variance function.

5. The beta-binomial distribution (`betabinomial`) arises by mixing the binomial distribution with the beta distribution, i.e. by assuming that the probability  $p$  of success of a binomial distribution follows a  $\text{beta}(\alpha, \beta)$  distribution. The mean and variance of the beta-binomial are given by  $n\pi$  and  $n\pi(1-\pi)(1 + \phi(n-1))$  respectively, in which  $n$  is the number of binomial trials, the probability  $\pi = \alpha/(\alpha+\beta)$ , and the dispersion parameter  $\phi = 1/(1+\alpha+\beta)$ . The back-transformation is given by  $\alpha = \pi(1-\phi)/\phi$  and  $\beta = (1-\pi)(1-\phi)/\phi$ . The `DISPERSION` parameter specifies the parameter  $\phi$  which must be in the interval  $(0,1)$ , and `MEAN` specifies the probability  $\pi$ .
6. The binomial-logit-normal distribution (`blogitnormal`) arises by assuming that the logit of the binomial probability  $p$  follows a normal distribution with mean  $\text{logit}(\pi)$  and variance equal to the dispersion parameter  $\phi$ . The resulting  $\text{logit}(p)$  is then back-transformed to the probability scale and conditionally on  $p$  the data are again binomially distributed. Alternative link functions for the logit-normal distribution can be specified by means of the `LINK` option. The `DISPERSION` parameter specifies the variance parameter  $\phi$  which must be positive. Note that the mean of this distribution does not equal  $n\pi$ .

The `DISTRIBUTION` option specifies the required distribution. The parameters `MEAN`, `NBINOMIAL` and `DISPERSION` specify the parameters of the distribution. The random numbers can be saved by means of the `NUMBERS` parameter. The `SEED` option can be set to initialise the random-number generator, hence giving identical results if the procedure is called again with the same options. If `SEED` is not set, generation will continue from the previous sequence in the program, or, if this is the first generation, the generator will be initialised by GenStat.

## Method

The GenStat commands to generate random numbers for the overdispersed distributions are basically given by

```

CALCULATE nrandom = NVALUES(MEAN)
CALCULATE index = 1/(DISPERSION-1)
CALCULATE gamma1 = GRGAMMA(nrandom ; MEAN*index ; 1/index)
CALCULATE opoisson = GRPOISSON(nrandom ; gamma1)
CALCULATE gamma2 = MEAN*GRGAMMA(nrandom ; 1/DISPERSION ; DISPERSION)
CALCULATE negativebinomial = GRPOISSON(nrandom ; gamma2)
CALCULATE sigma2 = LOG(DISPERSION + 1)
CALCULATE lambda = LOG(MEAN) - sigma2
CALCULATE meanPoisson = GRLOGNORMAL(nrandom ; lambda ; sigma2)
CALCULATE plognormal = GRPOISSON(nrandom ; meanPoisson)
CALCULATE alfa,beta = ((0,1) + (1,-1)*MEAN)*(1-DISPERSION)/DISPERSION
CALCULATE grbeta = GRBETA(nrandom ; alfa ; beta)
CALCULATE betabinomial = GRBINOMIAL(nrandom ; NBINOMIAL ; grbeta)
CALCULATE grnormal = ILOGIT(GRNORMAL(nrandom ; LOGIT(100*MEAN) ; \
DISPERSION))/100
CALCULATE blogitnormal = GRBINOMIAL(nrandom ; NBINOMIAL ; grnormal)

```

## Action with RESTRICT

The `NUMBERS` variate will only receive random numbers for those units to which `MEAN` is restricted. Values in the excluded units remain unchanged. Restrictions on the `NBINOMIAL` and `DISPERSION` parameters are not allowed and restrictions on the `NUMBERS` variate are ignored.

## CNTPROBABILITY

P.W. Goedhart

Calculates probabilities for an (overdispersed) count distribution

[contents](#) [previous](#) [next](#)

### Options

DISTRIBUTION = <i>string token</i>	Distribution for which probabilities must be calculated (poisson, oipoisson, negativebinomial, plognormal, power, binomial, betabinomial, blogitnormal); default poisson
LINK = <i>string token</i>	Link function for binomial-logit-normal distribution (logit, probit, complementaryloglog); default logit
POWER = <i>scalar</i>	Power in variance-to-mean relationship for the power distribution; default 1.5
METHOD = <i>string token</i>	Which probability to calculate (point, lower, upper). Cumulative probabilities are returned for settings lower (smaller than or equal) and upper (greater than); default point calculates point probabilities
NPOINTS = <i>scalar</i>	Number of Gauss-Hermite integration points for calculation of probabilities for the Poisson-lognormal and the Binomial-logit-normal distributions; default 128
ADAPTIVE = <i>string token</i>	Whether to apply adaptive Gauss-Hermite integration (yes, no); default yes

### Parameters

X = <i>scalars or variates</i>	Values for which probabilities must be calculated; must be set
MEAN = <i>scalars or variates</i>	Poisson mean $\mu$ or binomial probability $\pi$ of the count distribution; must be set
NBINOMIAL = <i>scalars or variates</i>	Number of binomial trials; must be set for a binomial type distribution
DISPERSION = <i>scalars or variates</i>	Dispersion parameter of overdispersed count distribution; must be set for an overdispersed distribution
PROBABILITY = <i>scalars or variates</i>	Saves the probabilities of the distribution; must be set

### Description

CNTPROBABILITY can be used to calculate probabilities for an (overdispersed) count distribution. The distribution can be either of the Poisson type (poisson, oipoisson, negativebinomial, plognormal, power) or the binomial type (binomial, betabinomial, blogitnormal), and this is set by the DISTRIBUTION option. These distributions, along with the definition of the DISPERSION parameter, are fully defined in the description of the CNTGRANDOM procedure. For the Poisson type distributions the MEAN parameter specifies the mean  $\mu$  of the distribution. For the binomial type distributions the MEAN parameter specifies the probability  $\pi$  of the distribution, and the NBINOMIAL parameter must be set to specify the number of binomial trials. The POWER option specifies the power  $p$  in the variance function of the power distribution.

The probabilities are saved in the PROBABILITY parameter for values contained in the X parameter. The possibly different means  $\mu$  are specified by the MEAN parameter, and the possibly different dispersion parameters by the DISPERSION parameter. The METHOD option specifies whether point or cumulative probabilities are calculated. Note that the upper setting calculates the probability of a value greater than X, similar to the probability functions of GenStat. Calculation of Poisson-Lognormal and binomial-logit-normal probabilities requires numerical integration. This is done by means of Gauss-Hermite integration, and the number of integration points can be specified by the NPOINTS option. Setting ADAPTIVE to the default value yes will generally increase numerical precision of Gauss-Hermite integration.

## Method

Cumulative lower probabilities for the overdispersed Poisson and the negbinomial distribution are calculated by means of the regularized incomplete beta function. The GenStat commands to do so are basically given by

```
CALCULATE LowerOpoisson = BETA(MU/(DISPERSION-1) ; X+1 ; 1/DISPERSION)
CALCULATE LowerNegBin   = BETA(1/DISPERSION ; X+1 ; 1/(1+MU*DISPERSION))
```

The lower probability for the Poisson-LogNormal distribution can be obtained by integrating out the normal random effect. The integral can be approximated by means of Gauss-Hermite integration:

$$P(Y \leq y) \approx \sum_j (w_j/\sqrt{\pi}) P[Z \leq y \mid Z \sim \text{Poisson}(\exp(\sqrt{2} \sigma x_j + \lambda))]$$

in which  $x_j$  are the so-called Gauss-Hermite nodes and  $w_j$  are the accompanying weights. Beta-binomial point probabilities are directly calculated by means of the `LNGAMMA` function. The lower probability of the binomial-logit-normal distribution is also obtained by Gauss-Hermite integration:

$$P(Y \leq y) \approx \sum_j (w_j/\sqrt{\pi}) P[Z \leq y \mid Z \sim \text{Binomial}(n, \text{logit}^{-1}(\sqrt{2} \sqrt{\phi} x_j + \text{logit}(\pi)))]$$

Point and upper probabilities can be obtained in a similar way.

## Action with RESTRICT

The `PROBABILITY` variate will only receive random numbers for those units to which `X` is restricted, and the saved `PROBABILITY` variate will be restricted accordingly. Values in the excluded units remain unchanged. Restrictions on the `MU`, `DISPERSION` and `PROBABILITY` parameter are not allowed.

## References

None.

## Procedures Used

`GAUSSPOINTS` is used to obtain the Gauss-Hermite integration points and weights.

## Similar Procedures

`CNTGRANDOM` generates pseudo-random numbers and `CNTSAMPLESIZE` calculates the sample size for an (overdispersed) count distribution.

## COMPACT

P.W. Goedhart

Compacts numerical vectors by storing unique rows and the number of times these occur

[contents](#) [previous](#) [next](#)

### Options

WEIGHTS = <i>variate</i>	Saves the weights, i.e. the number of times each row occurs in the original data
EXPAND = <i>factor</i>	Saves a factor that can be used to re-generate the original data
NEWVECTORS = <i>pointer</i>	Saves the new compacted vectors; if NEWVECTORS is not set the compacted values are saved in the VECTORS parameter

### Parameters

VECTORS = <i>variates</i> and/or <i>factors</i>	Numerical vectors that must be compacted
--	--

### Description

Procedure COMPACT can be used to generate a new dataset which has unique rows and to store the number of times each row occurs in the original dataset. This can for instance be used to speed up fitting of a generalized linear model, such as implemented in RBETABINOMIAL or RLOGITNORMAL, considerably. The VECTORS parameter specifies the numerical vectors that must be compacted. The new vectors can be saved by means of the NEWVECTORS options; if this is not set, the values of the VECTORS are replaced by the compacted structures. The WEIGHTS option can be used to save the number of times each row occurs in the original dataset. The EXPAND options can be used to save a factor which can be used to re-generate the original data; see the example program

### Method

First factors are formed from each variate and then the ordinal levels of all factors (formed and specified) are used to create a new factor which classifies the rows. The TABULATE directive is then used to compact the vectors.

### Action with RESTRICT

Restrictions are not allowed.

### References

None.

### Procedures Used

None.

### Similar Procedures

None.

### Example

```

CAPTION 'COMPACT example' ; STYLE=meta
VARIATE [VALUES=1,2,3, 1,2,3, 1,2,3, 1] variate ; DECIMALS=1
FACTOR [LABELS=!t(A, BB) ; VALUES=6(1), 4(2)] factor
COMPACT [WEIGHT=weight ; EXPAND=expand ; NEWVECTORS=new] variate, factor
PRINT expand, variate, factor ; FIELD=10,2(26)
PRINT weight, new[] ; FIELD=10,2(26)
PRINT expand, new[]$[expand] ; FIELD=10,2(26)

```

## D1INTERVAL

P.W. Goedhart

Plots multiple confidence intervals in a single graph

[contents](#) [previous](#) [next](#)

### Options

WINDOW = <i>scalar</i>	Window number for the plot; default 1
SCREEN = <i>string token</i>	Whether to clear the screen before plotting or to continue plotting on the old screen ( <i>clear</i> , <i>keep</i> ); default <i>clear</i>
TITLE = <i>text</i>	General title; default *
XTITLE = <i>text</i>	Title for the x-axis; default *
XLOWER = <i>scalar</i>	Lower bound for x-axis; default *
XUPPER = <i>scalar</i>	Upper bound for x-axis; default *
XMARKS = <i>variate</i>	Positions of the marks along the x-axis; default *
XLABELS = <i>text</i>	Label at each mark along the x-axis; default *
XTRANSFORM = <i>string token</i>	Transformed scale for the x-axis ( <i>identity</i> , <i>log</i> ); default <i>iden</i>
%LABELS = <i>scalar</i>	Percentage of the plot for the display of labels and group-labels; default -20
LABELSPOSITION = <i>variate</i>	Position of the labels and group-labels on a scale of 0-100; default !(25,10)
PLOT = <i>string tokens</i>	Which elements to plot ( <i>groups</i> , <i>grid</i> , <i>xmarks</i> , <i>percentages</i> , <i>values</i> , <i>outside</i> , <i>box</i> ); default <i>groups</i>
SPACINGS = <i>variate</i>	Spacings to be used; default !(0.75, 0.75, 0, 0.1, 0, 0, 0, 1.1)
PPOINTS = <i>pointer</i>	Pen definition of points; default *
PLINES = <i>pointer</i>	Pen definition of lines; default *
PLABELS = <i>pointer</i>	Pen definition of labels; default *

### Parameters

ESTIMATE = <i>variates</i>	Point estimates; has to be set
LOWER = <i>variates</i>	Lower confidence limits; has to be set
UPPER = <i>variates</i>	Upper confidence limits; has to be set
LABELS = <i>texts</i>	Label to display for each interval; default *
GROUPS = <i>factors</i>	Grouping of intervals with adjacent values; default *

### Description

Procedure D1INTERVAL plots estimates and confidence intervals, as specified by parameters ESTIMATE, LOWER and UPPER, as horizontal lines in a single graph. One-sided intervals can be defined by setting the appropriate LOWER or UPPER values to missing. Labels for the various intervals can be displayed by specifying the LABELS parameter and grouping of intervals is visualized in case the GROUPS parameter is set. Most elements of the plot can be modified, see below.

The WINDOW option defines the window in which the graph is drawn. This window is vertically split in two separate windows, one for the labels and groups-labels if requested, and one for the intervals. The size of the window for the labels is defined by the %LABELS option; a negative value will give rise to a label window on the left, a positive value to a window on the right. The position of the labels and group-labels within this window is defined by the LABELSPOSITION option; this must be set to a variate of length two. The default setting of !(25,10) will display the group-labels on the far left, at position 10 on a scale of 0 to 100, and the labels somewhat to the right of the group-labels, at position 25.

The SCREEN and TITLE options have their usual purpose. XTITLE specifies a title for the x-axis, and XLOWER and XUPPER can be used to specify the lower and upper bounds for the x-axis. If the bounds are unset all intervals will be fully displayed. Marks along the x-axis can be defined by means of the XMARKS option and accompanying labels can be set by the XLABELS option. The x-axis can be transformed to the log-scale by means of the XTRANSFORM option, in which case, when XLABELS is unset, only XMARKS larger than or equal to 1 are used as well as their reciprocals.

The PLOT option defines which additional elements are plotted. The groups setting displays the group-labels. The grid, xmarks and percentages setting are only active when the XMARKS option is set; grid displays vertical gridlines at each mark along the x-axis, xmarks display the x-axis labels above these gridlines, while percentages displays percentages increase and decrease above the gridlines (only applicable when the x-axis is log-transformed). The values setting plots the values of the estimates above the accompanying symbols, and the outside setting plots the values of the estimates which are outside the interval defined by XLOWER and XUPPER. Finally the box setting includes a box enclosing the entire plot. The SPACINGS option defines the following eight values: (1) distance to the x-axis of the bottom interval, (2) distance of intervals to the group divisor, (3) offset in the x-direction for PLOT=values, (4) offset in the y-direction for PLOT=values, (5) offset in the x-direction for PLOT=outside for estimates smaller than XLOWER, (6) offset in the x-direction for PLOT=outside for values estimates larger than XUPPER, (7) offset in the y-direction for PLOT=outside, and (8) the extra spacing required in case PLOT is set to xmarks or percentages. The default SPACINGS value is !(0.75, 0.75, 0, 0.1, 0, 0, 0, 1.1).

Most elements of the plot can be modified by setting the PPOINTS, PLINES and PLABELS pointers. It is advised to first call the procedure with these options set to undeclared structures, in which case no graph will be produced, and then to print the pointers to see their identifiers and values. The PPOINTS option defines the symbols for plotting ESTIMATES, LOWER and UPPER. The PLINES option defines line styles for the various lines, and the PLABELS options defines the way in which labels are plotted. The settings are defined in the tables below. In these tables 'CI' denotes the confidence interval, '[xlower, xupper]' is the interval defined by XLOWER and XUPPER, 'significant' are those intervals that do not cross the zero line, or the one line for a log-transform, symbol -5 is a triangle and symbol -6 is an arrow. Colours should be specified by numbers instead of by strings, e.g. by employing the RGB( ) function. Missing values will be replaced by default values as given in the tables below.

PPOINTS	Colour	Symbol	Size
1 – estimate for non-significant CI inside [xlower, xupper]	black	-3	1
2 – estimate for non-significant CI outside [xlower, xupper]	black	-5	1
3 – limit for non-significant CI inside [xlower, xupper]	black	-1	0.7
4 – limit for non-significant CI outside [xlower, xupper]	black	-6	0.7
5 – estimate for significant CI inside [xlower, xupper]	red	-3	1
6 – estimate for significant CI outside [xlower, xupper]	red	-5	1
7 – limit for significant CI inside [xlower, xupper]	red	-1	0.7
8 – limit for significant CI outside [xlower, xupper]	red	-6	0.7

PLINES	Colour	Linestyle	Thickness
1 – line for non-significant CI	black	1	1
2 – line for significant CI	red	1	1
3 – line for missing confidence limit for a non-significant CI	silver	2	1
4 – line for missing confidence limit for a significant CI	red	2	1
5 – vertical line at zero, or one for the log-transform	green	1	2
6 – horizontal lines between groups	darkgrey	1	1.5
7 – vertical gridlines	grey	2	1
8 – box	black	1	2

PLABELS	Colour	Size
1 – labels	black	0.8
2 – group-labels	black	1
3 – values for non-significant CI	black	0.7
4 – values for significant CI	red	0.7
5 – values outside the interval for non-significant CI	black	0.8
6 – values outside the interval for significant CI	red	0.8
7 – marks or percentages above the gridlines; default as pen -3	*	*

## Method

Standard GenStat facilities for graphical display are used.

## Action with RESTRICT

Restrictions are not allowed.

## References

None.

## Procedures Used

The subsidiary procedures %D11INTERVAL and %D12INTERVAL are called; these define the pens used in the procedure.

## Similar Procedures

D2INTERVAL plots multiple confidence along with limits of concern.

## D2INTERVAL

P.W. Goedhart

Plots multiple confidence intervals along with limits of concern in a single graph

[contents](#) [previous](#) [next](#)

### Options

WINDOW = <i>scalar</i>	Window number for the plot; default 1
SCREEN = <i>string token</i>	Whether to clear the screen before plotting or to continue plotting on the old screen ( <code>clear</code> , <code>keep</code> ); default <code>clear</code>
TITLE = <i>text</i>	General title; default *
XTITLE = <i>text</i>	Title for the x-axis; default *
XLOWER = <i>scalar</i>	Lower bound for x-axis; default *
XUPPER = <i>scalar</i>	Upper bound for x-axis; default *
XMARKS = <i>variate</i>	Positions of the marks along the x-axis; default *
XLABELS = <i>text</i>	Label at each mark along the x-axis; default *
XTRANSFORM = <i>string token</i>	Transformed scale for the x-axis ( <code>identity</code> , <code>log</code> ); default <code>iden</code>
%LABELS = <i>scalar</i>	Percentage of the plot for the display of labels and group-labels; default -20
LABELSPOSITION = <i>variate</i>	Position of the labels and group-labels on a scale of 0-100; default <code>!(25,10)</code>
PLOT = <i>string tokens</i>	Which elements to plot ( <code>groups</code> , <code>grid</code> , <code>xmarks</code> , <code>percentages</code> , <code>box</code> ); default <code>groups</code>
SPACINGS = <i>variate</i>	Spacings to be used; default <code>!(0.75, 0.75, 1, 1, 0.3, 1.1)</code>
COLOUR = <i>variate</i>	Colour to use for various symbols and lines
SYMBOL = <i>variate</i>	Symbol to use for various elements
SIZEMULTIPLIER = <i>variate</i>	Size in which to draw various symbols
LINESTYLE = <i>variate</i>	Style for various lines
THICKNESS = <i>variate</i>	Thickness with which various lines are drawn

### Parameters

ESTIMATE = <i>variates</i>	Point estimates; has to be set
LOWER = <i>variates</i>	Lower confidence limits; has to be set
UPPER = <i>variates</i>	Upper confidence limits; has to be set
LCLOWER = <i>variates</i>	Lower limits of concern; default *
LCUPPER = <i>variates</i>	Upper limits of concern; default *
LABELS = <i>texts</i>	Label to display for each interval; default *
GROUPS = <i>factors</i>	Grouping of intervals with adjacent values; default *
Alocs = <i>pointers</i>	Additional limits of concern; default *
AINTERVALS = <i>pointers</i>	Additional estimates and confidence limits; default *

### Description

Procedure D2INTERVAL plots estimates and confidence intervals, as specified by parameters ESTIMATE, LOWER and UPPER, as horizontal lines in a single graph. The plot is supplemented with limits of concern, specified by LCLOWER and LCUPPER, which are represented by vertical bars. Estimates and confidence limits inside the interval defined by the limits of concern are displayed in a different colour than values outside this interval, and so are estimates which are significantly different from zero. Labels for the various intervals can be displayed by specifying the LABELS parameter and grouping of intervals is visualized in case the GROUPS parameter is set. When only one limit of concern is specified, i.e. the accompanying other limit is set to missing, the interval is interpreted as one-sided and this is indicated by a different linestyle and a different symbol for the confidence limit that is unneeded. Additional limits of concern can be plotted by specification of the Alocs parameter; this should be set to variates with the same number of values as the ESTIMATE parameter. Moreover additional estimates and associated confidence intervals for each

primary interval can be plotted by setting the `AINTERVALS` parameter to a pointer with three variates. Most elements of the plot can be modified, see below.

The `WINDOW` option defines the window in which the graph is drawn. This window is vertically split in two separate windows, one for the labels and groups-labels if requested, and one for the intervals. The size of the window for the labels is defined by the `%LABELS` option; a negative value will give rise to a label window on the left, a positive value to a window on the right. The position of the labels and group-labels within this window is defined by the `LABELSPOSITION` option; this must be set to a variate of length two. The default setting of `!(25,10)` will display the group-labels on the far left, at position 10 on a scale of 0 to 100, and the labels somewhat to the right of the group-labels, at position 25.

The `SCREEN` and `TITLE` options have their usual purpose. `XTITLE` specifies a title for the x-axis, and `XLOWER` and `XUPPER` can be used to specify the lower and upper bounds for the x-axis. If the bounds are unset all intervals will be fully displayed. Marks along the x-axis can be defined by means of the `XMARKS` option and accompanying labels can be set by the `XLABELS` option. The x-axis can be transformed to the log-scale by means of the `XTRANSFORM` option, in which case, when `XLABELS` is unset, only `XMARKS` larger than or equal to 1 are used as well as their reciprocals.

The `PLOT` option defines which additional elements are plotted. The `groups` setting displays the group-labels. The `grid`, `xmarks` and `percentages` setting are only active when the `XMARKS` option is set; `grid` displays vertical gridlines at each mark along the x-axis, `xmarks` display the x-axis labels above these gridlines, while `percentages` displays percentages increase and decrease above the gridlines (only applicable when the x-axis is log-transformed). Finally the `box` setting includes a box enclosing the entire plot. The `SPACINGS` option defines the following six values: (1) distance to the x-axis of the bottom interval, (2) distance of intervals to the group divisor, (3) height of vertical lines for LOCs, (4) height of vertical lines for additional LOCs, (5) vertical spacing between the primary intervals and the additional intervals, and (6) the extra spacing required in case `PLOT` is set to `xmarks` or `percentages`. The default `SPACINGS` value is `!(0.75, 0.75, 1, 1, 0.3, 1.1)`.

Most elements of the plot can be modified by setting the `COLOUR`, `SYMBOL`, `SIZEMULTIPLIER`, `LINestyle` and `THICKNESS` variates. Missing values in these are replaced by default values. In the description below *NS* denote an estimate which is not significantly different from zero, *DIFF* denotes a significant estimate, *IN* denotes an interval which fully lies within the LOCS, *OUT* denotes an interval which does not fully lie within the LOCS, and *OUTX* denotes an estimate outside the interval defined by `XLOWER` and `XUPPER`.

The `COLOUR` option must be set to a variate with 16 values which defines colours for 1) *NS-IN* estimates, 2) *NS-OUT* estimates, 3) *DIFF-IN* estimates, 4) *DIFF-OUT* estimates, 5) *IN* confidence limits, 6) *OUT* confidence limits, 7) line for confidence interval, 8) vertical bars for LOCs, 9) colour band with LOCs, 10) vertical line for no difference, 11) horizontal lines for division of groups, 12) text in `LABELS`, 13) text in `GROUPS`, 14) vertical bars for additional LOCs, 15) line for additional confidence interval, and 16) vertical gridlines. Colours can be defined by means of the `RGB` function. Default colours correspond to the colours black, red, fuchsia, red, black, red, black, red, greenish, green, darkgrey, black, black, blue, black, grey.

The `SYMBOL` option must be set to a variate with 8 values which defines symbols for 1) estimates, 2) estimates *OUTX*, 3) confidence limits, 4) one-sided unneeded confidence limits, 5) additional estimates, 6) additional estimates *OUTX*, 7) additional confidence limits, 8) additional one-sided unneeded confidence limits. Default symbols are -4, -5, -1, 2, -4, -5, -1, 2, where -5 denotes a solid triangle.

The `SIZEMULTIPLIER` option must be set to a variate with 9 values which defines the size of 1) *NS-IN* estimates, 2) *NS-OUT* estimates, 3) *DIFF-IN* estimates, 4) *DIFF-OUT* estimates, 5) estimates *OUTX*, 6) confidence limits *IN*, 7) confidence limits *OUT*, 8) text in `LABELS`, 9) text in `GROUPS`. Default sizes are 1, 1, 1, 1, 1.5, 0.8, 0.8, 0.7, 1.

The `LINestyle` and `THICKNESS` options must be set to a variate with 11 values which defines the style and thickness of the line for 1) two-sided intervals, 2) one-sided intervals, 3) one-sided unneeded intervals, 4) vertical bars for LOCs, 5) vertical line for no difference, 6) horizontal lines for division of groups, 7) vertical bars for additional LOCs, 8) two-sided additional intervals, 9) one-sided additional intervals, 10) one-sided unneeded additional intervals, and 11) vertical gridlines. Default style of lines is 1, 1, 2, 1, 1, 1, 1, 1, 2, 2, while default thickness is 1, 1, 1, 2, 2, 2, 1, 1, 1, 1.

## D2KEYWINDOW

J.T.N.M. Thissen

Defines a keywindow inside another window

[contents](#) [previous](#) [next](#)

### Options

<i>XSIZE = scalar</i>	Size of keywindow in the x-direction as a percentage of the window; default 25
<i>YSIZE = scalar</i>	Size of keywindow in the y-direction as a percentage of the window; default 25
<i>XPOSITION = string token</i>	How to position the keywindow in the x-direction (left, centre, right); default right
<i>YPOSITION = string token</i>	How to position the keywindow in the y-direction (top, centre, bottom); default top
<i>BACKGROUND = scalar or text</i>	Specifies the colour to be used for the background of the keywindow; default 'white'
<i>BOX = string token</i>	Whether to include a box enclosing the keywindow (include, omit); default include
<i>FILLKEYWINDOW = string token</i>	Whether to fill the keywindow with the background colour (yes, no). This is especially useful when gridlines are plotted; default no

### Parameters

<i>WINDOW = scalar</i>	Window number for which a keywindow must be defined; default 1
<i>KEYWINDOW = scalar</i>	Window number for the key; default 11

### Description

D2KEYWINDOW defines a keywindow inside another window. The size of the keywindow, as a percentage of the size of the window, in both directions can be set by means of the *XSIZE* and *YSIZE* options. The position of the keywindow inside the other window can be set by means of the *XPOSITION* and *YPOSITION* options. The window for which the keywindow is defined must be set by the *WINDOW* parameter while the *KEYWINDOW* parameter specifies the window for the key. The background colour of the keywindow can be defined by the *BACKGROUND* option, while the *BOX* options allows you to put a box around the keywindow. The *FILLKEYWINDOW* can be used to fill the keywindow with the background colour which then 'hides' anything that is already plotted in the space occupied by the key.

The bounds of the axes of the keywindow are set to the interval [0,100] and the axes of the keywindow are hidden. This is accomplished by means of the following statement, and similarly for *YAXIS*:

```
XAXIS KEYWINDOW ; LOWER=0 ; UPPER=100 ; ACTION=hide
```

### Method

Standard facilities of GenStat are used.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

None.

### Similar Procedures

The *DKEY* procedure adds a key to a graph.

## DBBIPLOT

J.T.N.M. Thissen

Produces a high-resolution graphical biplot

[contents](#) [previous](#) [next](#)

### Options

<code>XUPPER = scalar</code>	Upper bound for x- and y-axis in the individuals plot
<code>VXUPPER = scalar</code>	Upper bound for x- and y-axis in the variates plot
<code>XMARKS = scalar or variate</code>	Distance between each tick mark on x- and y-axis (scalar) or positions of the marks in the individuals plot
<code>VXMARKS = scalar or variate</code>	Distance between each tick mark on x- and y-axis (scalar) or positions of the marks in the variates plot
<code>XTITLE = text</code>	Title for the x-axis in the individuals plot
<code>VXTITLE = text</code>	Title for the x-axis in the variates plot
<code>YTITLE = text</code>	Title for the y-axis in the individuals plot
<code>VYTITLE = text</code>	Title for the y-axis in the variates plot
<code>LABELS = text</code>	Labels at each point in the individuals plot
<code>VLABELS = text</code>	Labels at each point in the variates plot
<code>SYMBOLS = scalar, pointer, factor or text</code>	Plotting symbols: scalar for special symbols, pointer for user defined symbols, text or factor for character symbols
<code>VSYMBOLS = string token</code>	What to draw at the end of the line (arrowhead, line, none); default arrowhead
<code>COLOUR = scalar</code>	Number of the RGB colour used in the individuals plot
<code>VCOLOUR = scalar</code>	Number of the RGB colour used in the variates plot
<code>VLINESTYLE = scalar</code>	Style for the lines in the variates plot
<code>SCREEN = string token</code>	Whether to clear the screen before plotting the individuals plot or to continue plotting on the old screen (clear, keep); default clear
<code>VSCREEN = string token</code>	Whether to clear the screen before plotting the variates plot or to continue plotting on the old screen (clear, keep); default clear

### Parameters

<code>COORDINATES = matrices</code>	Scores for the individuals
<code>VCOORDINATES = matrices</code>	Scores for the variates

### Description

Procedure DBBIPLOT produces a high-resolution graphical biplot either by employing the saved results of the BIPLLOT procedure or by specifying explicitly the matrices of scores for individuals and for variates. Gabriel (1971) provides a full description of the technique. The scores for the individuals, contained in a matrix, must be specified by the COORDINATES parameter and the scores for the variates, also contained in a matrix, must be specified by the VCOORDINATES parameter. Although both matrices can have any dimension, only the first two columns are used. The options can be used to change the appearance of the graph. Option names starting with a `v` relate to the variates plot and the other options relate to the individuals plot.

The individuals plot is just a graph with the scores for individuals represented by dots (default) and labelled by numbers 1 to `n` (default). The dots are drawn with pen 1 and the labels with pen 2. Options SYMBOLS and LABELS can be used to change these default settings. If no labels are required the LABELS text structure should contain strings with spaces only.

The variates plot gives lines from each point to the origin. Option VSYMBOLS specifies what must be drawn at the end of the line. Option VLABELS can be used to label the lines. By default the letters of the alphabet are used. The lines are drawn with pen 3, the labels with pen 4 and the arrow-head or perpendicular line with pen 5. The other options are self explanatory.

It is not necessary to specify both matrices. This gives for instance the opportunity to extend biplots to triplots (Gower and Hand, 1996) by using DBBIPLOT twice. In that case the second biplot should have the option setting SCREEN=keep or VSCREEN=keep.

## Method

DBBIPLOT calculates the positions of the labels alongside the points for the individuals and the endpoints of the lines for the variates. Then points for the individuals and/or lines for the variates are plotted in the same graph.

## Action with RESTRICT

Not relevant.

BOXCOLOUR = <i>scalar or text</i>	Colour of box; default 'black'

### Parameters

FILENAMES = <i>texts</i>	Specifies which graphic files (.png, .jpg, .bmp or .tif) must be cropped; default * uses the graphic files which were produced with SETDEVICE
SIZES = <i>pointers</i>	Saves names of graphics files which are cropped and their old and new pixel widths and heights

### Description

Some of the graphic files saved by GenStat have white borders. This is the case for graphic files with extension .JPG, .JPEG, .TIF, .TIFF, .PNG and .BMP. Procedure DCROP can be used to crop these white borders. This procedure uses an external C# program. The graphic files for which to crop white borders can be specified by means of the FILENAMES parameter; the listed filenames must have one of the above extension. Alternatively, when FILENAMES is not specified, all graphic files produced by SETDEVICE are cropped. The PRINT option can be set to print the old and new pixel width and height of the cropped graphics files and the SIZES parameter can be set to save these. The NOMESSAGE option can be used to suppress various warning messages, e.g. when a filename does not exist.

The procedure first closes all graphics channel and then calls the external C# program. Due to possibly slow writing of graphical information to the graphics file after closing the graphics channel, the C# program is sometimes unable to crop the graphics file. This is especially so for large graphics files and/or slow computers. Therefore the procedure pauses GenStat before invoking the C# program so that all graphical information is written. The number of seconds to pause can be specified by means of the SECONDS option with default value 5. When the graphics files are produced by SETDEVICE with option setting ACTION2=synchronous the DCROP procedure does not pause because then the graph is created before executing any other command. This is therefore the recommend setting for ACTION2.

The MARGIN, LEFT, RIGHT, TOP and BOTTOM options allow to add a white border to the cropped image. The default margin in pixels as specified by the MARGIN option can be overridden by the other options. Note that option values lower than zero are set to zero, and values larger than 200 are set to 200. In addition to the white margin, a box can be drawn around the image by setting the BOXTHICKNESS option to a value larger than 0 (again a value larger than 200 is set to 200). The colour of the box can be specified by means of the BOXCOLOUR option which can be set to a scalar or a pre-defined colour.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

## Action with RESTRICT

Not relevant.

## References

None.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program and QTIMEDELAY is used to pause GenStat. The GenStat WORKSPACE of the SETDEVICE procedure with name 'BiometrisSetDevice' is assessed.

## Similar Procedures

Procedure SETDEVICE can be used to automatically open graphical files.

## Example

```
CAPTION 'DCROP example' ; STYLE=meta
SETDEVICE [PRINT=filename ; SURNAME='DcropExample']
DGRAPH !(1...10) ; !(1...10)
SETDEVICE [PRINT=filename]
DGRAPH !(1...5) ; !(1...5)
DCROP [PRINT=information]
```

## DIRLIST

P.W. Goedhart &amp; L.C.P. Keizer

Provides details about (wild-carded) files in a specified directory

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	What to print (filelist); default filelist
DIRECTORY = <i>text</i>	Single-valued text which specifies the directory for the file list; default *, i.e. the current working directory
SAVEDIRECTORY = <i>text</i>	Saves the full name of DIRECTORY
EXISTSDIRECTORY = <i>scalar</i>	Saves whether DIRECTORY exists (1) or not (0)
SUBDIRECTORIES = <i>text</i>	Saves the subdirectories of the specified directory
CASE = <i>string token</i>	Case to use for letters of SAVEDIRECTORY, SUBDIRECTORIES, NAME, SURNAME and EXTENSION (given, lower, upper, title); default given leaves the case of each letter unchanged
SINDEX = <i>string tokens</i>	Defines the ordering of the printed file list and of the saved parameters (name, surname, extension, size, date, time, attribute); default name
SDIRECTION = <i>string token</i>	Order in which to sort (ascending, descending); default ascending
NOMESSAGE = <i>string tokens</i>	Which warning messages to suppress (existdirectory, nofilesfound, duplicates); default *

### Parameters

FILES = <i>texts</i>	Files for file list, may contain wildcards * and ?, must not contain drives or directories
PRESENT = <i>variates</i>	Saves the number of files in each line of FILES; 0 indicates that the corresponding file is not present
NAME = <i>texts</i>	Saves the name of the files
SURNAME = <i>texts</i>	Saves the surname of the files, i.e. the name excluding the period and extension
EXTENSION = <i>texts</i>	Saves the extension of the files, excluding the leading period
SIZE = <i>variates</i>	Saves the size of the files in Kilobytes
DATE = <i>texts</i>	Saves the date of the files in format dd-mm-yyyy
TIME = <i>texts</i>	Saves the time of the files in format hh:mm:ss
ATTRIBUTE = <i>texts</i>	Saves the attributes of the files; this is a 4 letter string with successively r(eadonly), a(rchive), s(ystem), h(idden). A hyphen in any of these positions indicates that the specified attribute is off.

### Description

Procedure DIRLIST can be used to obtain information about files in a specified directory. It can also be used to obtain a wild-carded directory list. This procedure uses an external C# program. The directory can be specified by the DIRECTORY option; default is to look for files in the current working directory. Note that the double backslash (\\) is required in DIRECTORY because in GenStat a single "\" is treated as indicating a continuation on the next line. However, you can use a single "/" instead of the double backslash (\\).

The files for which information is required must be specified by the FILES parameter. The number of files present can be saved by the PRESENT parameter; this parameter is of the same length as FILES. Further information about the files can be saved by means of parameters NAME, SURNAME, EXTENSION, SIZE, DATE, TIME and ATTRIBUTE. These structures are all of length SUM(PRESENT), the length depends on whether files exist and whether wildcards are used. The full path of DIRECTORY can be saved by means of the SAVEDIRECTORY option. Option EXISTSDIRECTORY saves whether the DIRECTORY exists, and the SUBDIRECTORIES option can be used to save the subdirectories of the specified directory. In case the

directory does not exist or no files are found, all output structures, except EXISTDIRECTORY and PRESENT, are set to a single missing value.

The CASE option can be used to change the case of the saved text structures NAME, SURNAME, EXTENSION and SAVEDIRECTORY. The title setting of CASE changes the case of all letters to lowercase, except the first letter which is changed to uppercase. The SINDEXT option defines the ordering of the printed file list and of the saved parameters. The SDIRECTION option controls whether the ordering is into ascending or descending order. The default settings are SINDEXT=name and SDIRECTION=ascending.

The PRINT option controls printed output. The NOMESSAGE option can be used to suppress warning messages in case the DIRECTORY does not exist, when no FILES are found, or when duplicate file names have been removed from the listing.

## Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

## Action with RESTRICT

Restrictions on the DIRECTORY option and the FILES parameter are ignored.

## References

None.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

QDIRECTORY returns a directory selected by means of a directory browse dialog box on screen.

QFILENAME returns a single filename selected by means of a file open box on screen.

## Example

```

CAPTION 'DIRLIST example' ; STYLE=meta
DIRLIST [SAVEDIRECTORY=savedir ; CASE=title] FILES=!t('*.*)
PRINT savedir
TEXT files ; !t('*.ini', '*.hlp')
DIRLIST [PRINT=* ; DIRECTORY='C:/WINDOWS' ; EXISTDIRECTORY=exist] \
        FILES=files ; PRESENT=present ; NAME=name ; SURNAME=surname ; \
        EXTENSION=extension
PRINT files, present
IF exist .AND. SUM(present)
    PRINT name, surname, extension ; SKIP=3
ENDIF

```

## DORDINAL

J.T.N.M. Thissen

Plots and displays the results of a simple ordinal logistic regression model

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	Output required (curve, line, predictions, pairtest, items); default curve, line, predictions, pairtest
CTITLE = <i>text</i>	General title for the display of curves; default *
LTITLE = <i>text</i>	General title for the display of lines; default *
CYTITLE = <i>text</i>	Title for the y-axis in the display of curves; default *
LYTITLE = <i>text</i>	Title for the y-axis in the display of lines; default *
CXTITLE = <i>text</i>	Title for the x-axis in the display of curves; default *
LXTITLE = <i>text</i>	Title for the x-axis in the display of lines; default *
SCTITLE = <i>scalar</i>	Multiplier used in the calculation of the size in which to draw CTITLE; default 1
SLTITLE = <i>scalar</i>	Multiplier used in the calculation of the size in which to draw LTITLE; default 1
SCYTITLE = <i>scalar</i>	Multiplier used in the calculation of the size in which to draw CYTITLE; default 1
SLYTITLE = <i>scalar</i>	Multiplier used in the calculation of the size in which to draw LYTITLE; default 1
SCXTITLE = <i>scalar</i>	Multiplier used in the calculation of the size in which to draw CXTITLE; default 1
SLXTITLE = <i>scalar</i>	Multiplier used in the calculation of the size in which to draw LXTITLE; default 1
SORT = <i>string token</i>	Whether to sort the means in the diagram in ascending order (yes, no); default yes
XLGAP = <i>scalar</i>	Gap on the x-axis for the labels of the treatment factor; default 0.02
NPAGES = <i>scalar</i>	Number of pages for plotting the line plot

### Parameters

TREATMENTSTRUCTURE = <i>factor</i>	Defines the treatment factor of the model
BLOCKSTRUCTURE = <i>factor</i>	Defines the block factor of the model
TPROBABILITIES = <i>symmetric matrix</i>	Saves the t-probabilities of tests of pairwise comparisons
PREDPERCENTAGES = <i>pointer</i>	Saves the predictions in the categories expressed as percentages

### Description

Ordinal logistic regression can be performed by using the MODEL directive with option settings YRELATION=cumulative, DISTRIBUTION=multinomial and LINK=logit. This model is also called the proportional-odds model, see McCullagh & Nelder (1989). Procedure DORDINAL can be used to aid in the interpretation of the results of a simple ordinal logistic regression model, i.e. a model with only one treatment factor and possibly one block factor.

A call to DORDINAL must be preceded by an appropriate MODEL statement, a TERMS [FULL=yes] statement and a FIT statement. The TREATMENTSTRUCTURE and BLOCKSTRUCTURE parameters of DORDINAL should be set to the factors specified with TERMS and FIT. Plotting and printing of the results is controlled by the PRINT option with the settings: curve to display the fitted logistic distributions over the categories for each level of the treatment factor in a high-resolution plot (only when the number of levels of the TREATMENTSTRUCTURE factor is not greater than 20); line to display the distributions as a line between the 2.5% and 97.5% point of the logistic distributions; predictions to print the predicted percentages of the numbers of observations in each category; and pairtest to perform t-tests for all pairwise differences between the levels of the treatment factor. If pairtest is specified procedure PPAIR

with option `PRINT=groups` is used to print the diagram of significant differences; the `items` setting prints significant differences in another format (see procedure `PPAIR`). If the labels of the treatment factor are too long to fit in the default left hand side of the plot, the `XLGAP` option can be used to widen that gap. The `NPAGES` option can be used to span the line plots over multiple pages.

The t-probabilities of the tests of pairwise comparisons can be saved by parameter `TPROBABILITIES`. The `SORT` option controls whether the means in the diagram of `PPAIR` are sorted into ascending order. The predictions in the categories, expressed as percentages, can be saved by the `PREDPERCENTAGES` parameter. This parameter is a pointer (with length the number of categories) referring to variates with length the number of levels of the treatment.

All other options relate to the graphical environment of the plot. The `CTITLE` option can be used to provide a title for the graph of the curves and `LTITLE` for the graph of the lines. Titles can be added to the axes using the `CYTITLE`, `LYTITLE`, `CXTITLE` and `LXTITLE` options. By default the names of the category structures are plotted alongside the y-axis and the labels (or levels) of the treatment factor alongside the x-axis. The pensizes for the titles can be changed by using the options `SCTITLE`, `SLTITLE`, `SCYTITLE`, `SLYTITLE`, `SCXTITLE` and `SLXTITLE`.

## Method

Procedures `PAIRTEST` and `PPAIR` are used to test all pairwise comparisons between the levels of the `TREATMENTSTRUCTURE` factor. The saved fitted values are used to calculate the predictions, and the formula of the logistic distribution is used to plot the logistic curves and to display the line plot.

## Action with RESTRICT

Not relevant. The parameters `TREATMENTSTRUCTURE` and `BLOCKSTRUCTURE` are only needed to distinguish between the treatment and block factor.

## EDCONTINUOUS

*M.J.W. Jansen, J.C.M. Withagen & J.T.N.M. Thissen*

Calculates equivalent deviates for continuous distributions

[contents](#) [previous](#) [next](#)

### Options

DISTRIBUTION = <i>string token</i>	Type of distribution required (beta, gamma, lognormal, normal, uniform); default normal
METHOD = <i>string token</i>	Method by which the defining parameters of the distribution are specified (moments, quantiles); default moments
MEAN = <i>scalar</i>	Mean of distribution; default *
VARIANCE = <i>scalar</i>	Variance of distribution; default *
PROPORTIONS = <i>variate</i>	Two cumulative lower probabilities of distribution; default *
QUANTILES = <i>variate</i>	Two quantiles (equivalent deviates) corresponding to PROPORTIONS; default *
LOWER = <i>scalar</i>	Lower bound of beta, gamma, lognormal or uniform distribution; default 0
UPPER = <i>scalar</i>	Upper bound of beta or uniform distribution; default 1

### Parameters

CUMPROBABILITY = <i>variates</i> or <i>scalars</i>	Cumulative lower probabilities for which equivalent deviates are required; must be set
DEVIATE = <i>variates</i> or <i>scalars</i>	To save equivalent deviates corresponding to CUMPROBABILITY

### Description

Procedure EDCONTINUOUS calculates equivalent deviates corresponding to given cumulative lower probabilities for five continuous distributions: beta, gamma, lognormal, normal and uniform. The CUMPROBABILITY parameter specifies the cumulative lower probabilities and the corresponding equivalent deviates are saved by means of the DEVIATE parameter. The DISTRIBUTION option specifies the type of distribution. The METHOD option specifies how the parameters of the distribution are defined. When METHOD=moments the first two moments must be set by the MEAN and VARIANCE options. Alternatively, when METHOD=quantiles the distribution is characterised by a pair of cumulative lower probabilities with corresponding quantiles, and options PROPORTIONS and QUANTILES must be set. The uniform distribution is characterised by the LOWER and UPPER option settings, and other options are ignored. Lower and upper bounds for the other distributions can be specified by options UPPER and LOWER; these must be compatible with other option settings.

### Method

Internal calls are made to Genstat's ED-functions EDNORMAL, EDBETA and EDGAMMA. In most cases, the required ED-function parameters are derived from simple, well-known relations between ED-function parameters and moments or quantiles. However, when a beta or gamma distribution is specified by two quantiles, the ED-function parameters are derived by means of the FITNONLINEAR directive, which may cause numerical problems.

### Action with RESTRICT

Deviates are only calculated for the set of units to which CUMPROBABILITY is restricted. Other units will remain unaffected.

# EMMULTINORMAL

P.W. Goedhart

Estimates parameters of the multivariate normal distribution for data with missing values

[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string tokens</i>	Printed output required (pattern, monitoring, estimates); default pattern, estimates
MAXCYCLE = <i>scalar</i>	Maximum number of iterations for EM algorithm; default 200
TOLERANCE = <i>scalar</i>	Convergence criterion; default 1.0e-4

## Parameters

DATA = <i>pointers</i>	Pointer of variates with observed values
MEANS = <i>variates</i>	To save the estimate mean vector of the multivariate normal distribution
VCOVARIANCE = <i>symmetric matrices</i>	To save the estimate variance-covariance matrix of the multivariate normal distribution
EXPECTED = <i>pointers</i>	To save the expected values for missing data

## Description

Procedure EMMULTINORMAL estimates the parameters of the multivariate normal distribution for data with missing values using the EM algorithm. The DATA pointer specifies the variates for which parameters must be estimated. The estimates can be saved by means of the MEANS and VCOVARIANCE parameters. Missing values are replaced by conditional expected values in the EM algorithm and these can be saved by means of the EXPECTED parameter.

The EM algorithm is an iterative procedure and the maximum number of cycles and the convergence criterion can be set by MAXCYCLE and TOLERANCE. The PRINT options can be set to pattern to display the number of observations for each pattern of missing and non-missing values, to monitoring for convergence monitoring of the EM algorithm and to estimates to print the estimated parameters.

The algorithm can be very slow when there are many variates and/or many units.

## Method

Each iteration in the EM algorithm consists of two steps. The E-step of the algorithm computes the expected value of the sufficient statistics conditional on the observed values and the current parameter estimates. The M-step then uses the expected complete-data sufficient statistics to compute an update of the parameter estimates. This is iterated until the maximum of the relative difference of two subsequent estimates of the mean vector is less than the TOLERANCE convergence criterion. The algorithm starts with raw means, variances and covariances. Gelman et al (1995) gives a concise description of the algorithm for the multivariate normal distribution. To speed up the algorithm, the E-step is performed for all units with the same pattern of missing and non-missing values instead of for each unit separately.

## Action with RESTRICT

Restrictions on variates in the DATA pointer are not allowed.

## FDERIVATIVE

P.W. Goedhart

Calculates numerical derivatives of a function

[contents](#) [previous](#) [next](#)

### Options

CALCULATION = <i>expressions</i>	Expression structures to calculate the target function
PARAMETERS = <i>scalars</i>	Identifiers of the scalars, used by CALCULATION, which are arguments of the function
FUNCTION = <i>scalar</i>	Identifier of the scalar, calculated by CALCULATION, which defines the function value
DATA = <i>pointer</i>	Data to be used within the CALCULATION expressions or within the %FDERIVATIVE procedure
METHOD = <i>string token</i>	Numerical method to use ( <i>simple</i> , <i>ridders</i> ); default <i>simple</i>
STEPMETHOD = <i>string token</i>	Whether the steplength is absolute or relative with respect to the parameters ( <i>absolute</i> , <i>relative</i> ); default <i>relative</i>
STEPSIZE = <i>scalar</i>	Steplength to use in case the STEPLENGTH parameter is not set; default * uses 0.001 for the simple method and 0.1 for Ridders method
STEPTOLERANCE = <i>scalar</i>	Smallest absolute value for which a relative steplength must be used. Only relevant for STEPMETHOD= <i>relative</i> ; default 1.0
MAXCYCLE = <i>scalar</i>	Maximum number of iterations for Ridders method; default 20
TOLERANCE = <i>scalar</i>	Error criterion for exiting Ridders iterations; default 0 exits the iterative procedure when the global convergence criterion is satisfied

### Parameters

VALUES = <i>pointers</i>	Values for which the derivative of the function must be calculated; the pointer can be set to scalars, variates or unknown structures
STEPLENGTH = <i>pointers</i>	Steplengths to use for calculation of each derivative; default * uses the value as set by the STEPSIZE option
D1 = <i>pointers</i>	Saves the first order derivatives to the parameters in a pointer to variates
D2 = <i>pointers</i>	Saves the second order derivatives to the parameters in a pointer to variates
DMIXED = <i>pointers</i>	Saves the mixed second order derivatives to the parameters in a pointer to symmetric matrices
ERROR = <i>variates</i>	Saves an estimate of the error in the derivatives

### Description

FDERIVATIVE can be used to numerically approximate the first and second order derivatives of a function. The function can be specified either by setting the CALCULATION option to a list of GenStat expressions, or by defining a procedure %FDERIVATIVE which returns a function value. The METHOD option specifies the numerical procedure to be used. The *simple* setting uses  $[F(x+h) - F(x-h)]/(2h)$  to calculate the first order derivative, in which  $x$  is the value for which the derivative is required and  $h$  is a steplength. The second order derivative is then calculated by means of  $[F(x+h) + F(x-h) - 2F(x)]/(h^2)$ . The mixed second order derivative is only calculated when there are two parameters or more. It is calculated as  $[F(x+h, y+h) + F(x-h, y-h) - F(x-h, y+h) - F(x+h, y-h)]/(4h^2)$ , where  $x$  and  $y$  are the values for which the mixed derivative is required. The *ridders* setting employs Ridders (1982) algorithm which is a form of Richardson extrapolation. The latter method is more accurate and more time consuming since more function evaluations with increasingly smaller steplengths are used. The steplength  $h$  can be either absolute, as specified by the STEPMETHOD option, or relative in which case steps of  $h*x$  are used. However when  $Abs(x)$  is smaller than STEPTOLERANCE, the absolute steplength  $h$  is used. For METHOD=*ridders* the initial value of the steplength is not crucial although not too small values are to be used. Press et al (2002)

advice to set the steplength for Ridders method to a few tenth. For `METHOD=simple` the value of the steplength is crucial and it is advised to compare the derivatives for various steplengths.

In case the `CALCULATION` option is set to a list of expressions, the parameters used in these expressions must be specified by means of the `PARAMETERS` option and the `FUNCTION` option must be set to the resulting function value. The `DATA` option can be employed to provide any data structures that are used in the expressions to calculate the value of the function. The derivatives are calculated for values in the `VALUES` pointer. The length of this pointer should equal the length of the `PARAMETERS` list, and the pointer may contain variates and scalars. These values are processed row by row, and the derivatives with respect to each parameter are calculated. The `VALUES` pointer may contain an unknown structure, as specified by `*`, in which case the associated derivative is not calculated. In that case the corresponding value of the `PARAMETERS` list is used in the calculations. A general steplength can be specified by means of the `STEPSIZE` option. Alternatively parameter specific steplengths can be specified by means of the `STEPLENGTH` parameter, either as scalars or variates. The general steplength is used for scalars with a missing value in the `STEPLENGTH` parameter.

In case the `CALCULATION` option is not set, the user should provide a `%FDERIVATIVE` procedure which should return the function value for a set of parameters. The `DATA` option can then be employed to provide any data structures that are needed by `_FDERIVATIVE` to calculate the value of the function. In this case the `PARAMETERS` and `FUNCTION` option settings are not used. Details are given in the Methods section, and the Example section provides an example.

Derivatives can be saved by means of the parameters `D1`, `D2` and `DMIXED`. The length of the pointers `D1` and `D2` is the same as the length of the `VALUES` pointer, and the variates that are hold by these pointers have the same length as the number of rows in the `VALUES` pointer. The `DMIXED` pointer on the other hand contains symmetric matrices, one for each row in the `VALUES` pointer. The diagonal of each symmetric matrix in `DMIXED` is set to missing.

Ridders method provides an estimate of the error in the derivative. The `ERROR` parameter can be set to save, in a variate of length 2, the maximum error of all first order derivatives and the maximum of all second order derivatives. The maximum error is set to zero when `D1` and/or `D2` is unset. Ridders method is based on function values at increasingly smaller steplengths which results in higher order approximations of the derivative. The number of times the steplength is decreased is limited by the `MAXCYCLE` option. Moreover when the estimated error is smaller than the setting of `TOLERANCE` the iterative procedure is exited. By default, i.e. with `TOLERANCE=0`, the iterative procedure is stopped when the higher order approximation becomes worse.

## Method

The implementation of Ridders (1982) uses a transcript of the C++ algorithm `DFRIDR` in Press et al (2002). The skeleton of the `_DERIVATIVE` procedure, for calculation of more complex functions, is as follows

```
PROCEDURE [PARAMETER=pointer] '%FDERIVATIVE'
OPTION   'FUNCTION', 'DATA' ; TYPE='scalar', 'pointer' ; \
        SET=yes ; DECLARED=yes ; PRESENT=yes
PARAMETER 'PARAMETERS' ; TYPE='scalar' ; SET=yes ; DECLARED=yes ; PRESENT=yes
ENDPROCEDURE
```

This procedure should return the function value by means of the `FUNCTION` option for parameters as specified by the `PARAMETERS` option of `FDERIVATIVE`. The number of structures in the `VALUES` parameter of `FDERIVATIVE` should in principle be equal to the number of `PARAMETERS` used within `%FDERIVATIVE`.

## Action with RESTRICT

Variates in the `VALUES` and `STEPLENGTH` pointers should not be restricted.

## FEXPAND

J.T.N.M. Thissen

Forms a variate and/or factor by expanding a structure a specified number of times

[contents](#) [previous](#) [next](#)

### Options

None.

### Parameters

STRUCTURE = <i>identifiers</i>	Structure (scalar, variate, text, table, matrix, symmetricmatrix, diagonalmatrix) to be expanded
NOBSERVATIONS = <i>identifiers</i>	Numerical structure (scalar, variate, table, matrix, symmetricmatrix, diagonalmatrix) specifying the number of times each value of STRUCTURE must be expanded
VARIATE = <i>variates</i>	Variate to save the expanded values
FACTOR = <i>factors</i>	Factor to save the expanded values

### Description

Procedure FEXPAND expands the values of the STRUCTURE parameter a number of times as specified by parameter NOBSERVATIONS. Each value of the STRUCTURE parameter is copied as many times as the corresponding value of the NOBSERVATIONS parameter. The VARIATE and FACTOR parameters can be used to save the expanded structure as a variate and a factor. The STRUCTURE parameter can be set to a scalar, variate, text, table, matrix, symmetricmatrix or diagonalmatrix. If the STRUCTURE parameter is set to a text, output structure VARIATE must not be set. The NOBSERVATIONS parameter can be set to the same type of structures as the STRUCTURE parameter, with the exception of a text structure. The STRUCTURE and NOBSERVATIONS parameters must have the same number of values.

Missing values are not allowed in the NOBSERVATIONS parameter. If NOBSERVATIONS contains a zero the corresponding value of the STRUCTURE parameter is omitted.

### Method

The EXPAND function is used to calculate the new variate. The GROUPS directive is used to form the factor.

### Action with RESTRICT

Restrictions on the STRUCTURE and NOBSERVATIONS parameters are not allowed.

### References

None.

### Procedures Used

FTEXT and SUBSET.

### Similar Procedures

None.

**Example**

```

PRINT fmonth
TABULATE [CLASSIFICATION=fmonth ; PRINT=counts]
FACAMEND fmonth ; NEWLEVELS=!t(jan, feb, mar, apr)
TABULATE [CLASSIFICATION=fmonth ; PRINT=counts]
```

## FGRID

P.W. Goedhart

Forms a grid of values in one or more dimensions

[contents](#) [previous](#) [next](#)

### Options

VALUES = <i>numerical structures</i>	Values from which to form a grid of values; default *
MINIMUM = <i>numerical structure</i>	Minimum value of grid in each dimension; default 0
MAXIMUM = <i>numerical structure</i>	Maximum value of grid in each dimension; default 1
NGRID = <i>numerical structure</i>	Number of grid points in each dimension; default 11

### Parameters

GRID = <i>pointer</i>	To save the grid in a pointer to a set of variates
LEVELS = <i>pointer</i>	To save the distinct values of each grid variate

### Description

Procedure FGRID can be used to form a grid of numerical values in one or more dimensions. The grid may be specified in either of two ways. The first method is to set the grid points in each dimension by setting the VALUES option to a list of numerical structures. The dimension then equals the number of numerical structures in the VALUES list. The second method is to specify the MINIMUM and MAXIMUM value in each dimension. NGRID then specifies the number of grid points in each dimension. In this case the dimension equals the length of MINIMUM, which must equal the length of MAXIMUM. The length of NGRID must equal 1 or the length of MINIMUM. Note that the VALUES setting takes precedence over the other options. The GRID parameter saves the grid in a pointer to a set of variates. The LEVELS parameter can be used to save the distinct values of each grid variate.

### Method

The GenStat directive GENERATE is used to form the grid.

### Action with RESTRICT

Restrictions on the VALUES, MINIMUM, MAXIMUM and NGRID options are not allowed.

### References

None.

### Procedures Used

None.

### Similar Procedures

None.

### Example

```

CAPTION      'FGRID example' ; STYLE=meta

PRINT      grid[]
FGRID       [MINIMUM=0 ; MAXIMUM=10 ; NGRID=11] grid
PRINT      grid[]
FGRID       [MINIMUM=!( -10,0, 100) ; MAXIMUM=!(10,1,200) ; NGRID=!(5,3,2)] \
grid ; LEVELS=levels
PRINT      levels[], grid[]

```

# FINTEGRATE

P.W. Goedhart

Calculates a definitive integral of a function of one argument

[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string token</i>	Printed output required ( <i>area</i> ); default *
CALCULATION = <i>expressions</i>	Expression structures to calculate the function to be integrated
FUNCTION = <i>scalar</i>	Identifier of the scalar, calculated by CALCULATION, for which the integral must be calculated
DATA = <i>pointer</i>	Data to be used within the CALCULATION expressions or within the %FINTEGRATE procedure
METHOD = <i>string token</i>	Integration method to be used (trapezoidal, simpson, romberg, legendre); default legendre
NINTERVALS = <i>scalar</i>	Number of intervals into which the integration interval is subdivided or number of integration points for Gauss-Legendre integration; default 64
TOLERANCE = <i>scalar</i>	Convergence criterion for METHOD=Romberg; default 1.0e-4
NOMESSAGE = <i>string token</i>	Which message to suppress (warning); default *

## Parameters

PARAMETER = <i>scalar</i>	Identifier of the scalar argument, used by CALCULATION, of the function for which the integral must be calculated
LOWER = <i>scalars</i>	Lower integration limit
UPPER = <i>scalars</i>	Upper integration limit
AREA = <i>scalars</i>	To save the area of the function
SAVE = <i>pointers</i>	To save intermediate results for METHOD=Romberg

## Description

FINTEGRATE can be used to approximate the definitive integral of a function of one argument. The function for which the integral must be calculated can be defined by specifying a list of expressions with the CALCULATION option. The FUNCTION option defines the function value, say  $F(x)$ , that is calculated by the expressions as a function of the PARAMETER parameter, say  $x$ . The DATA option can be employed to provide any data structures that are used in the expressions to calculate the value of the function. The LOWER and UPPER parameters must be specified to define the integration interval and the resulting area can be saved by means of the AREA parameter.

The METHOD option specifies the integration method. All methods subdivide the integration interval into a number, as specified by the NINTERVALS option, of subintervals of equal length. More intervals provide better approximations of the integral. The area is approximated as a weighted sum of the function values at the subinterval endpoints. For the trapezoidal method the first and last weights are set to 1 and the other weights are equal to 1. This is equivalent to what is used by the AREA function of GenStat. For the simpson method the first and last weights equal 1/3 and the other weights alternate between 4/3 and 2/3. The romberg setting uses a form of Richardson extrapolation which is iterative such that subsequent iterations provide better approximation of the integral. The iterations are abandoned when successive approximations are within the value set by TOLERANCE. For METHOD=legendre Gauss-Legendre integration is used; in this case NINTERVALS specifies the number of integration points.

More complicated functions can be integrated by defining a procedure %FINTEGRATE, and not setting the CALCULATION option. This has the advantage that any GenStat commands can be used to obtain the function value. The DATA option can be employed to provide any data structures that are needed by %FINTEGRATE to calculate the value of the function. Details are given in the Methods section, and the Example section provides an example.

Printed output is controlled by the PRINT option. The NOMESSAGE option can be set to suppress a warning message when the iterative procedure for METHOD=romberg did not converge. The SAVE

parameter can be set for METHOD=romberg to save subsequent approximations of the integral in a symmetric matrix and convergence information.

## Method

The trapezoidal and Simpson rules for approximating an integral are well known. Simpson's rule is generally more accurate than the trapezoidal rule. Romberg integration is even more precise and also provides an estimate of error. The implementation of Romberg's method follows closely the algorithm in [http://en.wikipedia.org/wiki/Romberg's\\_method](http://en.wikipedia.org/wiki/Romberg's_method). The relative error of Romberg's method is calculated as the quotient of the absolute error and the current best approximation bounded by 1. The iterative scheme is abandoned when either the absolute or relative error is smaller than the tolerance. For Gauss-Legendre integration see the GAUSSPOINTS procedure. The skeleton of the \_FINTEGRAL procedure, for integrating more complex functions, is given below. Note that the parameters are of type variate.

```
PROCEDURE '%FINTEGRATE'
  OPTION      'DATA' ; TYPE='pointer' ; SET=no ; DECLARED=yes ; PRESENT=yes
  PARAMETER  'PARAMETER', 'FUNCTION' ; TYPE='variate' ; SET=yes ; \
            DECLARED=yes,no ; PRESENT=yes,no
ENDPROCEDURE
```

## Action with RESTRICT

Not relevant.

## References

None.

## Procedures Used

GAUSSPOINTS. The subsidiary procedure %FINTEGRATE is used.

## Similar Procedures

GAUSSPOINTS can be used to calculate Gauss-Hermite and Gauss-Legendre integration points.

  FINTEGRATE [DATA=data ; METHOD=#method] \
            LOWER=lower ; UPPER=upper ; AREA=area[ii]
ENDFOR
PRINT     aExact, area[] ; FIELD=18 ; DECI=12
```

# FISHEREXACT

P.W. Goedhart

Performs pairwise tests of independence of rows in a  $r \times 2$  table[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string token</i>	What to print (probabilities); default probabilities
METHOD = <i>string token</i>	Type of test required (twosided, lessthan, greater); default twosided
SORT = <i>string token</i>	Whether to sort the observed proportions in ascending order (no, yes); default no

## Parameters

XBINOMIAL = <i>variates</i>	Observed binomial counts
NBINOMIAL = <i>variates</i>	Binomial totals
LABELS = <i>texts</i>	Text vector naming the elements of XBINOMIAL; if LABELS is unset the unit numbers of XBINOMIAL are used; default *
TWOSIDED = <i>symmetric matrices</i>	To save the tail probabilities of the test statistic corresponding to METHOD=twosided
LESSTHAN = <i>symmetric matrices</i>	To save the tail probabilities of the test statistic corresponding to METHOD=lessthan
GREATER = <i>symmetric matrices</i>	To save the tail probabilities of the test statistic corresponding to METHOD=greater

## Description

Fisher's exact test is an unbiased uniformly most powerful test of independence in a  $2 \times 2$  table (Kendall and Stuart, 1979). It is particularly useful for tables with small marginal counts because the approximation of other test statistics, such as chi-squared and likelihood ratio, is poor for such tables. The test is most easily explained when one classifying factor is simply a labelling of two populations (e.g. smokers and non smokers), and the two populations are to be compared with respect to the probability of having an attribute (e.g. lung cancer). More formally, let  $x_1$  and  $x_2$  be two independent binomial distributions,  $x_1 \sim \text{Binomial}(n_1, p_1)$  and  $x_2 \sim \text{Binomial}(n_2, p_2)$ , for which the equality of probabilities  $p_1$  and  $p_2$  is to be tested. Fisher's exact test uses the test statistic  $(x_1 | x_1 + x_2 = r)$ , which follows, assuming  $p_1 = p_2$ , a hypergeometric distribution with parameters  $(N = n_1 + n_2, n_1, r)$ .

The XBINOMIAL parameter specifies the observed binomial counts ( $x_1, x_2, x_3, \dots$ ) while NBINOMIAL specifies the binomial totals ( $n_1, n_2, n_3, \dots$ ). FISHEREXACT performs all pairwise tests of equality of probabilities ( $p_1, p_2, p_3, \dots$ ). The METHOD option, with default setting *twosided*, specifies which type of test is performed:

<i>twosided</i>	gives two-sided tests for	$H_0 : p_i = p_j$	for $i < j$
<i>lessthan</i>	gives one-sided tests for	$H_0 : p_i \leq p_j$	for $i < j$
<i>greater</i>	gives one-sided tests for	$H_0 : p_i \geq p_j$	for $i < j$

where  $i$  and  $j$  number the elements of XBINOMIAL. Twosided probabilities are calculated as the minimum of 1 and twice the smaller of the two tail probabilities. Tail probabilities can be saved in symmetric matrices TWOSIDED, LESSTHAN and GREATER. These matrices are labelled by the first 9 characters of the text vector LABELS or, if this is unset, by the unit numbers of XBINOMIAL.

The PRINT option controls the output of FISHEREXACT. By default a symmetric matrix with tail probabilities is printed with the observed percentages ( $100 \times \text{XBINOMIAL} / \text{NBINOMIAL}$ ) on the diagonal. The SORT option controls whether the percentages on the diagonal are sorted into ascending order. Combining SORT=yes with METHOD=lessthan is particularly useful.

## Method

The standard GenStat functions CLHYPERGEOMETRIC and CUHYPERGEOMETRIC are used to calculate the hypergeometric probabilities.

## Action with RESTRICT

Pairwise tests are only performed for the set of units to which XBINOMIAL is restricted. Restrictions on NBINOMIAL and LABELS are ignored.

## FMINIMIZE

P.W. Goedhart

Minimizes a function of one parameter argument by (modified) golden section search

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	Printed output required (minimum, monitoring); default minimum, monitoring
CALCULATION = <i>expressions</i>	Expression structures to calculate the target function
FUNCTION = <i>scalar</i>	Identifier of the scalar, calculated by CALCULATION, whose value is to be minimized
DATA = <i>pointer</i>	Data to be used within the CALCULATION expressions or within the %FMINIMIZE procedure
METHOD = <i>string token</i>	Optimization method (brent, mbrent, goldensectionsearch); default brent
MAXCYCLE = <i>scalar</i>	Maximum number of iterations; default 50
TOLERANCE = <i>scalar</i>	Convergence criterion; default 1.0e-4
NOMESSAGE = <i>string token</i>	Which message to suppress (warning); default *
_PRINT = <i>texts</i>	To modify the printed monitoring of the iterative procedure); default *

### Parameters

PARAMETER = <i>scalars</i>	Identifier of the scalar argument, used by CALCULATION, of the function to be minimized
LOWER = <i>scalars</i>	Lower limit of the parameter which is used for initial bracketing of the minimum
UPPER = <i>scalars</i>	Upper limit of the parameter which is used for initial bracketing of the minimum
MINIMUM = <i>scalars</i>	To save the minimum of the function
FUNCTIONVALUE = <i>scalars</i>	To save the function value at the minimum
SAVE = <i>pointers</i>	To save (intermediate) results of the iterative procedure

### Description

FMINIMIZE can be used to find the minimum of a function in a given interval, similar to the MIN1DIMENSION procedure. The minimum is found by golden section search possibly combined with parabolic interpolation. The function to be minimized can be defined by specifying a list of GenStat expressions with the CALCULATION option, similarly to the way in which functions for optimization are specified for the FITNONLINEAR directive. The FUNCTION option defines the function value that is calculated by the expressions as a function of the PARAMETER parameter. The DATA option can be employed to provide any data structures that are used in the expressions to calculate the value of the function. The LOWER and UPPER parameters must be specified to define the interval in which to search for the minimum. The results of the minimization can be saved by means of the MINIMUM, FUNCTIONVALUE and SAVE parameters.

The minimization method can be specified by the METHOD option. Options setting brent uses the BRENT algorithm in Press et al (2002). Setting mbrent uses a modified version in which the bracketing interval is narrowed after each parabolic fit. Setting goldensectionsearch only uses golden section search without parabolic interpolation. The MAXCYCLE option sets a limit on the number of iterations. The TOLERANCE option controls the convergence criterion; convergence is reached when the bracketing interval [a,b] is such that  $(b-a) < (a+b)*TOLERANCE$ .

More complicated functions can be minimized by defining a procedure %FMINIMIZE, and not setting the CALCULATION option. This is more complicated to specify, but it has the advantage that any GenStat command can be used to obtain the function value. The DATA option can be employed to provide any data structures that are needed by %FMINIMIZE to calculate the value of the function. Details are given in the Methods section, and the Example section provides an example.

Printed output is controlled by the PRINT option. The NOMESSAGE option can be set to suppress a warning message when the iterative procedure did not converge. Printed monitoring information can be modified by setting the \_PRINT option to two texts; see the source code of the procedure for details.

## Method

FMINIMIZE performs a series of iterations in which three points are moved in one dimension to locate the minimum. The idea is that the two outer points should bracket the minimum, while the inner point locate it. Golden section search derives its name from the fact that the algorithm maintains the function values for triples of points whose distances form a golden ratio. Brent's (1973) modification to this algorithm uses parabolic interpolation whenever possible to speed up convergence. The procedure is a transcript of the C++ algorithm BRENT in Press et al (2002). The parabolic fit is omitted when golden section search is used. The skeleton of the %FMINIMIZE procedure, for minimizing more complex functions, is as follows

```
PROCEDURE '%FMINIMIZE'
OPTION      'FUNCTION', 'DATA' ; TYPE='scalar', 'pointer' ; \
           SET=yes,no ; DECLARED=no,yes ; PRESENT=no,yes
PARAMETER  'PARAMETER' ; TYPE='scalar' ; SET=yes ; DECLARED=no ; PRESENT=no
ENDPROCEDURE
```

The options and parameter of this procedure are identical to those of FMINIMIZE.

## Action with RESTRICT

Not relevant.

## FPOINTER

L.C.P. Keizer &amp; J.T.N.M. Thissen

Forms a pointer from a text structure

[contents](#) [previous](#) [next](#)

### Options

SCOPE = *string token*

This allows pointer elements within a procedure to be set to point to structures in the program that called the procedure (SCOPE=external) or in the main program itself (SCOPE=global); default global

### Parameters

TEXT = *texts*

Names of the structures to be stored in POINTER

POINTER = *pointers*

To save the pointer structure

### Description

Procedure FPOINTER can be used to form a pointer from a text structure. This is especially useful for procedure writers who retrieve information about structures in a text structure, e.g. by using procedure QPICKLIST. The strings in the TEXT parameter define the structures (identifiers) of the POINTER parameter. The SCOPE option is similar to that of the ASSIGN directive.

### Method

Directive ASSIGN, with the SCOPE option set, is printed to a text structure and then executed.

### Action with RESTRICT

If the TEXT parameter is restricted, the POINTER is formed from the restricted text.

### References

None.

### Procedures Used

FTEXT.

### Similar Procedures

RENAMEPOINTER renames the structures of a pointer.

### Example

```

CAPTION 'FPOINTER example' ; STYLE=meta
UNIT [10]
FACTOR Treat
READ Treat, Time[1...3], Weight ; FREPRESENTATION=labels,4(*)
A 91.7 12.4 44.3 41.0 B 91.7 11.3 35.4 36.5
C 92.4 9.5 48.6 44.4 D 91.8 10.4 39.9 37.1

```

# FPRODUCT

J.T.N.M. Thissen

Forms a factor with a label for every combination of other factors

[contents](#) [previous](#) [next](#)

## Options

SPACE = *string token* Whether to use spaces between the labels of the factors (yes, no); default yes

## Parameters

FACTORS = *pointers* or *formulae* Factors contributing to each product  
 PRODUCT = *factors* Factors to be formed  
 FREPRESENTATION = *texts* Defines how the labels of the PRODUCT factor are formed from the values of the FACTORS parameter (labels, levels, ordinals); default is to use labels of the FACTORS if available and levels otherwise  
 IDENTIFIER = *texts* Whether to represent the identifier of the factors from the FACTORS parameter into the labels of the PRODUCT factor (yes or no); default \* uses the identifier only for factors without labels  
 LABELS = *texts* Text structure to save the labels of the PRODUCT factor

## Description

Procedure FPRODUCT is a modified version of the FACPRODUCT procedure from the official Procedure Library. FPRODUCT allows a factor to be formed whose labels represent all the combinations of a list of other factors. Parameter PRODUCT specifies the identifier of the factor to store the product, and parameter FACTORS gives the list of factors from which it is to be formed. These factors can be input in either a pointer or a model formula.

The labels of the PRODUCT factor are defined by the settings of the parameters FREPRESENTATION and IDENTIFIER. The length of the FREPRESENTATION and IDENTIFIER text structures should equal the length of the FACTORS pointer, or should be equal to 1 in which case the specification is for each factor. Each string of the FREPRESENTATION text structure can be set to ordinals, levels or labels indicating the way in which the factor levels appear in the labels of the PRODUCT factor. Each string of the IDENTIFIER text structure can be set to yes or no indicating whether the corresponding factor name precedes the factor level in the label. Default is to use the identifier only for factors which have no labels.

By default the labels of the factors are separated by one or more spaces. Setting option SPACE=no suppresses all spaces. The labels of the PRODUCT factor can be saved by the LABELS parameter.

## Method

The FCLASSIFICATION directive is used, if necessary, to form lists of factors whose product is to be calculated. The labels for the new factor are formed by printing the labels (or levels and whether or not with identifier) of the factors of the FACTORS parameter into one text structure. The GROUPS directive is then used to form the new factor.

## Action with RESTRICT

If any of the factors is restricted, the labels will be formed only for the units not excluded by the restriction.

## References

None.

## Procedures Used

CHECKARGUMENTS is used to check that all the elements of the FACTORS pointer are factors. FTEXT is used to form text structures from the factors and SUBSET is used in case the factors are restricted.

## Similar Procedures

FACPRODUCT forms a factor with a level for every combination of other factors.

## FROOTFIND

P.W. Goedhart

Finds the root of a function of one parameter argument by (modified) bisection

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	Printed output required ( <i>root</i> , <i>monitoring</i> ); default <i>root</i>
CALCULATION = <i>expressions</i>	Expression structures to calculate the target function
FUNCTION = <i>scalar</i>	Identifier of the scalar, calculated by CALCULATION, for which the root must be found
DATA = <i>pointer</i>	Data to be used within the CALCULATION expressions or within the %FROOTFIND procedure
METHOD = <i>string token</i>	Method to be used to find the root ( <i>bisection</i> , <i>ridders</i> ); default <i>bisection</i>
MAXCYCLE = <i>scalar</i>	Maximum number of iterations; default 100
TOLERANCE = <i>variate</i>	Convergence criterion for root and function value; default $!(1.0e-4, 1.0e-6)$
NOMESSAGE = <i>string token</i>	Which message to suppress ( <i>warning</i> ); default *
_PRINT = <i>texts</i>	To modify the printed monitoring of the iterative procedure); default *

### Parameters

PARAMETER = <i>scalars</i>	Identifier of the scalar argument, used by CALCULATION, of the function for which the root must be found
VALUE = <i>scalars</i>	Defines the root to be found, i.e. the root is the parameter for which the function value equals this setting; default 0
LOWER = <i>scalars</i>	Lower limit of the parameter which is used for initial bracketing of the root
UPPER = <i>scalars</i>	Upper limit of the parameter which is used for initial bracketing of the root
ROOT = <i>scalars</i>	To save the root of the function
FUNCTIONVALUE = <i>scalars</i>	To save the function value at the root
SAVE = <i>pointers</i>	To save (intermediate) results of the iterative procedure

### Description

FROOTFIND can be used to find the root of a function in a given interval. The root is found using bisection possibly combined with a variant on false position (or regula falsi). The function for which the root must be found can be defined by specifying a list of GenStat expressions with the CALCULATION option, similarly to the way in which functions for optimization are specified for the FITNONLINEAR directive. The FUNCTION option defines the function value, say  $F(x)$ , that is calculated by the expressions as a function of the PARAMETER parameter, say  $x$ . The root  $z$  is defined by  $F(z) = y$  and the value of  $y$  can be specified by means of the VALUE parameter. The default value for the VALUE parameter equals zero. The DATA option can be employed to provide any data structures that are used in the expressions to calculate the value of the function. The LOWER and UPPER parameters must be specified to define the interval in which to search for the minimum. The results of the root finding can be saved by means of the ROOT, FUNCTIONVALUE and SAVE parameters.

The root finding method can be specified by the METHOD option. The default setting is *bisection*, while the *ridders* setting uses the ZRIDDR algorithm in Press et al (2002). The MAXCYCLE option sets a limit on the number of iterations. The TOLERANCE option controls the convergence criterion. The iterative procedure is either exited when the current bracketing interval  $[a,b]$  is such that  $(b-a)/\text{Max}(\text{Abs}(a+b);1)$  is less than the first element of the TOLERANCE option or when  $(F(z)-y)/\text{Max}(\text{Abs}(y);1)$  is smaller than the second element of the TOLERANCE option.

More complex functions can be minimized by defining a procedure %FROOTFIND, and not setting the CALCULATION option. This is more complicated to specify, but it has the advantage that any GenStat

commands can be used to obtain the function value. The DATA option can be employed to provide any data structures that are needed by %FROOTFIND to calculate the value of the function. Details are given in the Methods section, and the Example section provides an example.

Printed output is controlled by the PRINT option. The NOMESSAGE option can be set to suppress a warning message when the iterative procedure did not converge. Printed monitoring information can be modified by setting the \_PRINT option to two texts; see the source code of the procedure for details.

## Method

The bisection method performs a series of iterations which repeatedly bisects an interval and then selects a subinterval in which the required root must lie. Bisection is robust but slow. According to Press et al (2002) Ridder's (1979) method is a powerful variant of bisection which assumes that the function is approximately linear in the region of interest. Ridder's method is a transcript of the C++ algorithm ZRIDDR in Press et al (2002). Generally speaking Ridder's method will require less function evaluations than bisection. The skeleton of the %FROOTFIND procedure, for minimizing more complex functions, is as follows

```
PROCEDURE '%FROOTFIND'
OPTION 'FUNCTION', 'DATA' ; TYPE='scalar', 'pointer' ; \
      SET=yes ; DECLARED=yes ; PRESENT=yes
PARAMETER 'PARAMETER' ; TYPE='scalar' ; SET=yes ; DECLARED=yes ; PRESENT=yes
ENDPROCEDURE
```

The options and parameter of this procedure are identical to those of FROOTFIND.

## Action with RESTRICT

Not relevant.

## FSUBFACTOR

L.C.P. Keizer &amp; J.T.N.M. Thissen

Forms a factor to index the units within another factor

[contents](#) [previous](#) [next](#)

### Options

METHOD = *string token*                      How to index the levels of the factor (`global`, `local`). Setting `local` uses the order of the values of FACTOR; default `global`

### Parameters

FACTOR = *factors*                              Factor within whose levels the levels of SUBFACTOR are formed; must be set

SUBFACTOR = *factors*                         To save the formed factor; must be set

GROUPS = *factors*                             To save the factor of new groups if METHOD=`local`

### Description

Procedure FSUBFACTOR can be used to index the units within the levels of the FACTOR parameter. The indexed units are saved in the factor specified by the SUBFACTOR parameter. The METHOD option defines how to index the levels of the factor. The default setting `global` takes each level of FACTOR in turn, and numbers the corresponding units of SUBFACTOR as 1 to the number of occurrences of that level. The setting `local` uses the order of the values of FACTOR. First a new factor, saved by the GROUPS parameter, is created which has a new level each time the value of FACTOR changes. The units are then indexed within the newly formed factor. The GROUPS parameter can only be saved for METHOD=`local`.

### Method

FSUBFACTOR uses standard GenStat directives for data manipulation.

### Action with RESTRICT

If the FACTOR parameter is restricted the SUBFACTOR and GROUPS factor are restricted in the same way. The indices of the SUBFACTOR and GROUPS parameter are determined by the levels of FACTOR not excluded by the restriction. SUBFACTOR and GROUPS values excluded by the restriction are set to missing.

### References

None.

### Procedures Used

None.

### Similar Procedures

AFUNITS forms a factor to index the units of the final stratum of a design.

### Example

```

CAPTION      'FSUBFACTOR example' ; STYLE=meta
FACTOR       [LEVELS=3 ; VALUES=6(3,1,2)] Blocks
FACTOR       [LEVELS=2 ; VALUES=3(1,2)2,3(2,1)] Plots
FPRODUCT    !P(Blocks, Plots) ; BlockPlots
FSUBFACTOR  Blocks ; WithinB
FSUBFACTOR  BlockPlots ; WithinBP
PRINT       Blocks, Plots, BlockPlots, WithinB, WithinBP
FACTOR       [LEVELS=3 ; VALUES=2(1...3),1,4(2),6(3),1,2,3] factor
FSUBFACTOR  [METHOD=local] FACTOR=factor ; SUBFACTOR=subfact ; GROUPS=groups
FSUBFACTOR  FACTOR=groups ; SUBFACTOR=subfactnew
PRINT       factor, groups, subfact, subfactnew

```

# FUNIQUETEXT

L.C.P. Keizer &amp; J.T.N.M. Thissen

Forms a text with unique strings from another text

[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string token</i>	What to print (information); default information
STRING = <i>text</i>	Text structure of length 1 specifying the character(s) between the string of OLDTEXT and added number; default '_'
JUSTIFICATION = <i>string token</i>	How to position the numbers within the field ( <i>right</i> , <i>left</i> ); default <i>right</i>

## Parameters

OLDTEXT = <i>texts</i>	Text structure whose strings must be made unique; must be set
NEWTEXT = <i>texts</i>	To save the text with the newly formed unique strings
UNIQUESTRINGS = <i>texts</i>	To save the text with the unique strings of OLDTEXT
CHECK = <i>scalars</i>	To save whether OLDTEXT is already unique (1) or not (0)

## Description

Procedure FUNIQUETEXT can be used to form a text structure NEWTEXT with unique strings from an existing text structure OLDTEXT. If the NEWTEXT parameter is not specified the OLDTEXT structure is overwritten by the new text structure. The non-unique strings of the OLDTEXT parameter are extended with numbers separated by the character(s) of the STRING option, so the lengths of NEWTEXT and OLDTEXT are equal. Before determining the unique strings leading and trailing spaces are removed. If the same string occurs in OLDTEXT more than 9 times, the added numbers can be right or left justified by setting the JUSTIFICATION option. The unique strings of OLDTEXT can be saved by the UNIQUESTRINGS parameter. The CHECK parameter saves whether the OLDTEXT parameter is already unique (1) or not (0).

The default setting *information* of the PRINT option prints a message in case there are no duplicate strings in the OLDTEXT parameter.

## Method

The procedure uses directive CONCATENATE.

## Action with RESTRICT

If the OLDTEXT parameter is restricted, the NEWTEXT parameter is restricted in the same way. Values in units excluded by the restriction are not altered if NEWTEXT is unset. If NEWTEXT is set the excluded units in NEWTEXT are empty.

## References

None.

## Procedures Used

None.

## Similar Procedures

None.

**Example**

```
CAPTION 'FUNIQUETEXT example' ; STYLE=meta

FUNIQUETEXT [JUSTIFICATION=left] OLDTEXT=letters ; NEWTEXT=newleft
FUNIQUETEXT [STRING='..'] OLDTEXT=letters ; NEWTEXT=newdots
FUNIQUETEXT [STRING=' ' ; JUSTIFICATION=left] OLDTEXT=letters ; \
NEWTEXT=newnothing ; UNIQUESTRINGS=unique
PRINT letters, newleft, newright, newdots, newnothing ; FIELD=12
PRINT unique ; FIELD=12
```

## GAUSSPOINTS

P.W. Goedhart

Calculates the nodes and weights for Gauss-Hermite and Gauss-Legendre integration

[contents](#) [previous](#) [next](#)

### Options

METHOD = <i>string token</i>	Which integration points to return (hermite, legendre); default hermite
NPOINTS = <i>scalar</i>	Number of integration points. The procedure takes very little time when this is set to a power of 2 or to 196; default 32
MULTIPLY = <i>string token</i>	Whether to multiply the Gauss-Hermite integration points with the squared root of 2 and the weights with the reciprocal of the squared root of pi (yes, no); default yes

### Parameters

NODES = <i>variate</i>	To save the integration points
WEIGHTS = <i>variate</i>	To save the weights

### Description

Gauss-Hermite integration can be used to approximate a specific integral, with integration limits  $-\infty$  and  $\infty$ , as follows:

$$\text{Integral}(F(x) \exp(-x^2); -\infty; \infty) = \sum_j w_j F(x_j)$$

in which  $x_j$  are the so-called nodes and  $w_j$  are the weights. It follows that, for the normal density function  $\phi$  with mean  $\mu$  and variance  $\sigma^2$ :

$$\text{Integral}(F(x) \phi(x); -\infty; \infty) = \sum_j (w_j / \sqrt{\pi}) F(\sqrt{2} \sigma x_j + \mu)$$

Gauss-Legendre integration can be used to approximate the following integral, with integration limits  $-1$  and  $1$ , as follows:

$$\text{Integral}(F(x); -1; 1) = \sum_j w_j F(x_j)$$

Gauss-Hermite and Gauss-Legendre integration with  $N$  integration nodes are both exact for polynomial functions up to order  $(2N-1)$ .

The integration points to return is specified by the METHOD option. The number of nodes must be specified by means of the NPOINTS option and the nodes and weights are saved by the NODES and WEIGHTS parameters. The maximum number of nodes is 196 for Gauss-Hermite and 1024 for Gauss-Legendre. In case NPOINTS is set to a power of 2 or to 196, hard-coded results are returned to speed up computation. For Gauss-Hermite integration the MULTIPLY option can be used to modify the saved nodes and weights to enable their direct use for integration with the normal density.

### Method

The procedure is a transcript of the C++ algorithms GAUHER and GAULEG in Press et al (2002). A GenStat WORKSPACE with name 'BiometrisGaussPoints' is used to save the current integration points for fast retrieval between successive calls with the same option settings.

### Action with RESTRICT

Not relevant.

# GENBATCH

P.W. Goedhart &amp; L.C.P. Keizer

Runs several GenStat programs simultaneously in batch

[contents](#) [previous](#) [next](#)

## Options

NPROCESSORS = <i>scalar</i>	Number of batch jobs to run simultaneously. This must be set to a value smaller than or equal to the number of processors in your PC; default 0 employs $\frac{3}{4}$ of the number of available processors
DIRECTORY = <i>text</i>	In which directory to save all the output and intermediate files in case of a simulation study; default *, i.e. the current working directory
CLEARDIRECTORY = <i>string token</i>	Whether to delete all files in DIRECTORY before running the programs or not (yes, no). Only relevant when DIRECTORY is set; default no
DELETE = <i>string tokens</i>	Which files to delete after completion of all simulation jobs (input, output, backingstore, warning); default *, i.e. none
OUTEXTENSION = <i>text</i>	Which file extension to use for output files; default lis
OUTWIDTH = <i>scalar</i>	Width of output files; default 86
BACKEXTENSION = <i>text</i>	Which file extension to use for backingstore files; default bst
SETTINGS = <i>variate</i>	Simulation settings, i.e. unit numbers of the DATA structures, to invoke. Only relevant when PROGRAM is set to a single-valued text; default *, i.e. all simulation settings are invoked
CONTINUE = <i>string token</i>	Whether to continue an incomplete simulation or to redo specific simulations as specified by the REDO option (yes, no). Only relevant when PROGRAM is set to a single-valued text; default no
REDO = <i>string tokens</i>	Which simulation settings to redo in addition to those which were not run before (stopped, warning, fault, error). Only relevant when CONTINUE=yes; default stopped
TITLE = <i>text</i>	Single-valued text structure specifying the title of the Windows form; default * uses the surname of the first file of the PROGRAM parameter
MESSAGE = <i>text</i>	Single-valued text structure specifying an additional message for the Windows form; default *, i.e. none
EXIT = <i>string token</i>	Whether to exit the Windows form on completion of all batch jobs (yes, no); default yes
COLOUR = <i>text or scalar</i>	Colour to use for the progress bar in the Windows form; default 'lime'
POSITION = <i>string token</i>	Position of the Windows form (tl, tc, tr, cl, cc, cr, bl, bc, br) The first letter stands for top, centre and bottom, the second for left, centre, right; default br
WAIT = <i>string token</i>	Whether to wait for the completion of the current simulation before continuing execution of GenStat (no, yes). The setting yes is useful to queue multiple simulations; default no

## Parameters

PROGRAM = <i>text</i>	Programs to run in batch; these must refer to existing files
DATA = <i>pointer</i>	Data to be passed when PROGRAM is set to a single-valued text for a simulation study; the pointer can only contain variates, factors and/or texts with the same number of values

## Description

Procedure GENBATCH can be used to run several GenStat programs simultaneously in batch using an external C# program. The number of simultaneous jobs can be specified by means of the NPROCESSORS option. This is especially useful for running multiple programs on a PC with multiple cores and/or threads since GENBATCH is able to utilize all available resources. Consequently, running time might be decreased

considerably. It is advised to study and run the example program for a full understanding of the working of the GENBATCH procedure. Also some timing with different settings of NPROCESSORS is advised. There are two important notes:

1. Using all available processors might, after some time, results in Windows memory problems. The default setting NPROCESSORS=0 employs  $\frac{3}{4}$  of the available processors which seems a sensible setting.
2. The order in which the jobs are run is rather random as a so-called thread pool is used in C#.

The first and simplest way to use GENBATCH is when multiple GenStat programs must be run. Suppose that "P1.gen" and "P2.gen" are these multiple programs. The PROGRAM parameter of GENBATCH can then be set to the text structure !t('P1.gen', 'P2.gen'). This will invoke two calls to GenBatch.exe with parameters respectively "IN=P1.gen, OUT=P1.lis/86" and "P2.gen, P2.lis/86". So the GenStat output is written to files "P1.lis" and "P2.lis" respectively, both with an output width of 86. The extension of the output files and their width can be modified by setting the OUTEXTENSION and OUTWIDTH options. The progress of the jobs is monitored by a Windows form with a progress bar and timing information. Also the number of jobs with a GenStat warning message will be displayed in green, while the number of jobs with a GenStat fault is displayed in red. The title of the Windows form can be set by means of the TITLE option and the MESSAGE option can be used to display an additional message in the form. The colour of the progress bar can be set by the COLOUR option and the POSITION option determines the initial position of the form. By default the form will be closed on completion of all batch jobs, but this can be changed by specifying EXIT=no. The form can also be closed manually, using the customary close button, which will result in killing all jobs which were not completed. Clicking the progress bar in the form will partly minimize and un-minimize the form, and there is also the usual minimize button. Note that the number of processors to use can be changed in the Windows form. It can even be set to zero in which case processing of jobs will be paused (after completion of the currently running jobs). While pausing, the PC can even be put to sleep or to hibernate, and running of jobs can be continued after waking up the PC. Timing information will be written to a file with the same surname as the first program with "-Info" appended to it. So in the example above this file will be named "P1-Info.lis".

The second way is when a single program must be called with different settings of one or more data structures, as in a simulation study. The PROGRAM parameter must then be set to this single GenStat program, say "Simulation.gen", and the data structures can be passed by means of the DATA pointer. Suppose that the DATA pointer consists of a single variate called alfa with say 10 values. The procedure first creates a backingstore file called "Simulation.bst" with the values of the DATA pointer in the "data" subfile. Next for every simulation setting, i.e. for every value of alfa, a separate backingstore file is created with the single value of alfa stored in the "setting" subfile. These backingstore files are called "Simulation-01.bst", "Simulation-02.bst", ... , "Simulation-10.bst". Then a GenStat program "Simulation-Batch.gen" is generated with the following program lines added to the start of the program "Simulation.gen":

```
RETRIEVE [CHANNEL=6 ; SUBFILE=setting] pointer
DUMMY    alfa ; pointer[1]
```

Finally GenBatch.exe is invoked ten times with argument

```
IN=Simulation-Batch.gen, OUT=Simulation-##.lis/86, BS6= Simulation-##.bst
```

in which is ## is set to 01, 02 , ... , 10. So the added program lines at the start of the program will retrieve the simulation settings as scalars from the separate backingstore files (or single-valued texts when the DATA pointer contains a text structure). After completion of all jobs a dedicated GenStat program is run. This will write monitoring and timing information to an output file "Simulation.lis", and will also store the monitoring information in a subfile named "completed" in "Simulation.bst". Moreover the GenStat program will loop over all separate backingstore files to see if any results of the simulation are saved in the default subfile. If this is the case the results are stored in a subfile named "results" in "Simulation.bst", see the example program. In addition a GenStat program "Simulation-Retrieve.gen" is created; this is a skeleton program to retrieve structures from "Simulation.bst".

There are some extra options which are specific to a simulation study. The DIRECTORY option can be used to store all input, output and backingstore files which are created by GENBATCH in a separate directory rather than in the working directory. The CLEARDIRECTORY option can be set to yes to empty this

directory before running the programs. The `DELETE` option, which should be used with great care, can be used to delete these input, output and backingstore files after completion of all jobs. These files are only deleted for simulations which are completed without a GenStat warning or fault. The warning setting of `DELETE` can be used to additionally delete files for simulation settings which generated a GenStat warning. The `SETTINGS` option can be used to limit the simulations to specific unit numbers of the `DATA` structures. An incomplete simulation study can be continued by specifying `CONTINUE=yes`. This will perform simulations that are not invoked previously, with code `Exit=0`, e.g. because the `SETTINGS` options was used. Moreover it will also redo simulations as specified by the `REDO` option. By default `REDO=stopped` and all simulations which were stopped by exiting the Windows form are run again; these simulations have code `Exit=-1`, see below. In addition, setting the `REDO` option to `warning`, `fault` and/or `error` will redo simulations which generated a GenStat warning (code `Exit=2`), a GenStat fault (code `Exit=-2`) or another error (code `Exit<-2`) respectively. The `BACKEXTENSION` option can be set to specify the extension of all backingstore files used by `GENBATCH`.

Finally the `WAIT` option can be used to queue multiple simulations. For instance

```
GENBATCH [WAIT=yes] 'Sim01.gen' ; DATA=data01
GENBATCH [WAIT=no]  'Sim02.gen' ; DATA=data02
STOP
```

Will first perform the first simulation using multiple processors without continuing to the second simulation. When the first simulation has finished the second simulation is started and GenStat continues to the `STOP` directive.

## Method

The `SUSPEND` directive is used to invoke an external C# .NET Framework 3.5 program. In C# the “ThreadPool.QueueUserWorkItem” is employed to put all jobs in a queue. For a simulation program the subfile named “completed” in “Simulation.bst” contains a pointer named `completed`. This pointer contains a variate named `Exit` with the following exit codes for every simulation setting:

0	Not run before	-1	FAULT: Stopped by user
1	Successful	-2	FAULT: GenStat Fault in program
2	Successful with GenStat warnings	-3	FAULT: GenBatch.exe error
		-4	FAULT: Unknown GenBatch.exe error
		-5	FAULT: C# program error

Note that `Exit=-1` is not really a fault but rather a result of stopping one or more simulations by manually exiting the Windows form which monitors the progress of the simulation.

## Action with RESTRICT

The `PROGRAM` and `DATA` parameters should not be set to restricted structures.

## References

A skeleton of the C# program is given in <http://www.dotnetperls.com/threadpool>.

## Procedures Used

The `BIOMETRIS` procedure is used to retrieve the filename of the external C# program. `SFILENAME` is also used. Three subsidiary procedures are employed by `GENBATCH`: `%GB4MULTIPLE`, `%GB5GETRANGE` and `%GB6COLLECTRESULTS`. The latter is used to collect simulation results.

## Similar procedures

None.

## GMULTIVARIATE

M.J.W. Jansen, J.C.M. Withagen &amp; J.T.N.M. Thissen

Generates pseudo-random numbers from multivariate normal or Student's t distribution

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	Whether to print a summary ( <i>summary</i> ); default * prints no output
DISTRIBUTION = <i>string token</i>	Type of distribution required ( <i>normal, student</i> ); default <i>normal</i>
NVALUES = <i>scalar</i>	Number of values to generate; default 1
MEANS = <i>variate</i>	The mean for the multivariate Normal or Student's t distribution; default is a variate with values all equal to 0
VCOVARIANCE = <i>diagonal or symmetric matrix</i>	The variance-covariance matrix for the multivariate Normal or Student's t-distribution; default is to use an identity matrix
DF = <i>scalar</i>	Number of degrees of freedom for Student's t distribution; default *
SEED = <i>scalar</i>	Seed to generate the random numbers; default 0 continues an existing sequence or initialises the sequence automatically if no random numbers have been generated in this job

### Parameters

NUMBERS = <i>pointers or matrices</i>	Saves the random numbers as either a pointer to a set of variates or a matrix
---------------------------------------	---

### Description

Procedure GMULTIVARIATE generates pseudo-random numbers from a multivariate Normal or from a multivariate Student's t distribution. The type of distribution can be set by the DISTRIBUTION option. The mean  $\mu$  is specified by the option MEANS as a variate of length  $p$ ; the variance-covariance matrix  $\Sigma$  is specified by the option VCOVARIANCE as a diagonal or symmetric matrix with  $p$  rows and columns; and the option NVALUES specifies the number of values to be generated. Note that VCOVARIANCE must be positive semi-definite. The DF option must be used to specify the number of degrees of freedom for the Student distribution and must be at least 3.

The SEED option can be set to initialise the random-number generator, hence giving identical results if the procedure is called again with the same options. If SEED is not set, generation will continue from the previous sequence in the program, or, if this is the first generation, the generator will be initialised by CALCULATE.

The numbers can be saved using the NUMBERS parameter, in either a pointer to a set of variates, or a matrix. If the NUMBERS structure or structures are already declared, their dimensions must be compatible with the settings of the NVALUES, MEANS and VCOVARIANCE options. The dimensions are also used, if necessary, to set defaults for the options. By default, MEANS is taken to be a variate of zero values, and VCOVARIANCE is taken to be the identity matrix. If the setting of NUMBERS is not already declared, it will be defined as a pointer to a set of variates with dimensions deduced from the option settings.

### Method

Pseudo-random numbers from a multivariate Normal distribution are generated by forming a matrix  $Y$  of columns of univariate Normal random numbers, using the Box-Muller method (Box & Muller 1958), followed by a linear transformation

$$X = A Y + \mu,$$

where  $A$  is calculated by a Choleski decomposition,  $AA' = \Sigma$ . See, for example, Johnson (1987, pages 52-55) or Tong (1990, pages 181-186). Pseudo-random numbers from the multivariate Student distribution are generated according to the definition of the multivariate Student distribution:

$$t(\mu, \Sigma, df) \sim \mu + MN(0, \Sigma) / \text{Sqrt}(\text{Chi-squared}(df)/df)$$

where  $MN(0, \Sigma)$  is multivariate normal with mean 0 and variance-covariance  $\Sigma$ ; and where the scalar  $\text{Chi-squared}(df)$  has a chi-square distribution with  $df$  degrees of freedom. See, for example, Box &

Tiao (1973). Note that the variance-covariance matrix of the multivariate Student distribution equals  $[df / (df - 2)] \text{Sigma}$ .

### Action with RESTRICT

Variates that have been restricted will receive output from GMULTIVARIATE only in those units that are not excluded by the restriction. Values in the excluded units remain unchanged. Note that the NVALUES option must equal the full size of the variates. Restrictions on the MEANS variate are ignored.

## GRUBBSTEST

P.W.Goedhart

Performs Grubbs' test for a single outlier

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	Whether to print the test results ( <i>test</i> ); default <i>test</i>
METHOD = <i>string token</i>	Type of test ( <i>twosided</i> , <i>minimum</i> , <i>maximum</i> ); default <i>twosided</i>
SAVE = <i>pointer</i>	To save results of Grubbs' test
POSITION = <i>pointer</i>	To save the positions of the possible outlier in each variate

### Parameters

SAMPLE = *variates*                      Variates for which Grubbs' test is performed

### Description

Procedure GRUBBSTEST can be used to detect a single outlier in a sample that follows a normal distribution. Grubbs' test is also known as the maximum normed residual test. By default a two-sided test is performed in which either the sample minimum or maximum is the outlier. A one-sided test, i.e. whether the minimum or maximum is an outlier, is obtained by employing the METHOD option. The test statistics and associated probability, along with the number of values, the mean and standard deviation, are printed. The possible outlier is also printed along with the symbol – or + when this is the minimum or maximum. Results can be saved by setting the SAVE option and the positions of the possible outlier in each variate can be saved by setting the POSITION option. Note that multiple positions can occur, e.g. when two units have the same value.

### Method

The Grubbs' test statistic is the largest absolute deviation from the sample mean in units of the sample standard deviation. The associated probability is derived from inverting the critical value, and this probability is bounded by one. The test statistic is set to missing whenever there are 2 or less observations or when the standard deviation equals zero.

### Action with RESTRICT

Restrictions on a SAMPLE variate will be obeyed.

## GUNITCUBE

M.J.W. Jansen, J.C.M. Withagen & J.T.N.M. Thissen

Generates pseudo-random numbers from a distribution with marginal uniform distributions

[contents](#) [previous](#) [next](#)

### Options

NVALUES = <i>scalar</i>	Number of values to generate; default 1 or deduced from the NUMBERS parameter
RCORRELATION = <i>scalar</i> or <i>symmetricmatrix</i>	Required rank correlation matrix of multivariate distribution; default is the identity matrix
SEED = <i>scalar</i>	Seed to generate the random numbers; default 0 continues an existing sequence or initializes the sequence automatically if no random numbers have been generated in this job
STRATIFICATION = <i>string token</i>	Stratification (none, latin); default none
METHOD = <i>string token</i>	Method to achieve rank correlation (simple, iman); default simple

### Parameters

NUMBERS = <i>pointers</i> or <i>matrices</i>	Saves the random numbers as either a pointer to a set of variates or a matrix
--	---

### Description

Procedure GUNITCUBE generates pseudo-random numbers from a multivariate distribution with marginal distributions that are uniform on the interval from 0 to 1, and with a given rank-correlation matrix RCORRELATION. The numbers can be saved using the NUMBERS parameter, in either a pointer to a set of variates, or a matrix. If the NUMBERS structures are already declared, their dimensions must be compatible with the settings of the NVALUES and RCORRELATION options. Otherwise the dimensions of the NUMBERS pointer are deduced from these options. The dimensions of NUMBERS are also used, if necessary, to set defaults for the options. If NUMBERS is not declared in advance, RCORRELATION must be set. By default RCORRELATION is taken to be the identity matrix. If the setting of NUMBERS is not already declared, it will be defined as a pointer to a set of variates with dimensions deduced from the option settings.

An ordinary random sample is obtained by the option settings STRATIFICATION=none and METHOD=simple. Option setting STRATIFICATION=latin can be used to obtain Latin-hypercube samples, with marginal sample distributions that are very nearly uniform, while option setting METHOD=iman imposes close resemblance between the sample correlation matrix and RCORRELATION.

If RCORRELATION is set, the required rank correlation will be introduced according to the specified METHOD option (thus, METHOD has no effect if RCORRELATION is unset). The combination of RCORRELATION set to an identity matrix and METHOD=simple is stochastically equivalent to RCORRELATION unset.

To avoid values very close to 0 and 1, NUMBERS smaller than 0.000005 and larger than 0.999995 are set to these respective limits.

### Method

The method to construct a latin hypercube sample stems from McKay et al (1979). The method to introduce the required rank correlation stems from Iman & Conover (1982).

### Action with RESTRICT

Any restrictions on variates of the NUMBERS pointer will be cancelled and all units will be used.

## IRCLASS

A. Keen

Fits a generalized linear mixed model to grouped response variables, e.g. to ordinal data

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	Printed output required (model, components, effects, means, stratumvariances, monitoring, vcovariance, Waldtests, deviance); default components, effects, stratumvariances
UDISTRIBUTION = <i>string token</i>	Underlying distribution (logistic, normal, evleft, evright, lognormal, student); default logistic
DF = <i>scalar</i>	Degrees of freedom for DISTRIBUTION=student; default * i.e. the number of degrees of freedom is estimated
CUTPOINTS = <i>scalars</i>	Fixed values for the cutpoints; default *
MULINK = <i>string token</i>	Link function relating the mean of the underlying distribution to the linear predictor (identity, logarithm, power); default identity
EXPONENT = <i>scalar</i>	Exponent for power link; no default, i.e. must be set
UDISPERSION = <i>scalar</i>	Value of dispersion of the underlying distribution; default 1
INTERCEPT = <i>string token</i>	How to treat constant (estimate, omit); default estimate
CADJUST = <i>string token</i>	What adjustment to make to covariates before analysis (mean, none); default mean
FIXED = <i>formula</i>	Fixed effects model for the mean of the underlying distribution; default *
RANDOM = <i>formula</i>	Random effects model for the mean of the underlying distribution; default *
ABSORB = <i>factor</i>	Absorbing factor; default *
INITIAL = <i>scalars</i>	Initial values for variance components; default *
CONSTRAINTS = <i>string token</i>	How to constrain each variance component (positive, fixrelative, fixabsolute); default positive
FDISPERSION = <i>formula</i>	Fixed effects model for the logarithm of the standard deviation of the underlying distribution
RDISPERSION = <i>formula</i>	Random effects model (with fixed variance component) for the log standard deviation of the underlying distribution
IDISPERSION = <i>scalars</i>	Initial value for the variance of the parameters of RDISPERSION; default 0.1
PSE = <i>string tokens</i>	Standard errors to be printed with tables of effects and means (differences, estimates, alldifferences, allestimate, none); default differences
VCCONVERGENCE = <i>scalar</i>	Variance component for fixed non-linear effects to be used as a tool for improving convergence; default 1000
MAXITER = <i>scalar</i>	Maximum number of REML iterations; default 50
MAXCYCLE = <i>scalar</i>	Maximum number of cycles within each REML; default 5

### Parameters

YCOUNTS = <i>pointer</i>	Pointer of variates with numbers of observations in each of the classes
YCLASS = <i>variate</i>	Response variate of observed class numbers for each unit
FITTEDVALUES = <i>pointer</i>	To save fitted frequencies in the different classes if YCOUNTS is set and expected class number if YCLASS is set
UMEANS = <i>variate</i>	To save estimated means of the underlying distribution
LINEARPREDICTOR = <i>variate</i>	To save the linear predictor, i.e. means at the link scale
VCOVARIANCE = <i>symmetric matrix</i>	To save the variance-covariance matrix for the estimates of the variance components
ALLVCOVARIANCE = <i>symmetric</i>	To save the variance-covariance matrix for the full set of fixed and

<i>matrix</i>	random effects not associated with the absorbing factor
PREDICTIONS = <i>pointer</i>	To save estimates of random effects
SE PREDICTIONS = <i>pointer</i>	To save estimates of standard errors of the predictions

## Description

A generalized linear mixed model (GLMM) is specified for the underlying variable in a threshold model. For ordinal data, when cutpoints are estimated, the residual variance is fixed at a default value, e.g. 1 for the normal distribution. In case cutpoints are known, the residual variance is estimated. In addition to the more traditional models with normal random effects, many other distributions with extra shape parameters may be fitted to the data. For instance, the residual variance may be modelled on the log scale, to allow for variance heterogeneity.

Most options of IRCLASS are similar to the options of GenStat directives MODEL, VCOMPONENTS and REML. The PRINT option is similar to the PRINT option of REML, however monitoring information is always printed. The PSE option is as in REML. Because the only relevant distribution is the multinomial one, option DISTRIBUTION of the MODEL directive is omitted. Option UDISTRIBUTION of the IRCLASS procedure defines the composite link function that links the mean of observed counts to the mean of the underlying distribution. UDISTRIBUTION therefore replaces option LINK of the MODEL directive, which is not used in IRCLASS, to avoid confusion. Option MULINK links the mean of the underlying distribution to the linear predictor scale. Included is the power link for continuous distributions defined at the positive axis, like the lognormal distribution. No link function is allowed for distributions defined on the whole real axis. Underlying distributions allowed are the logistic, normal, evleft, evright, lognormal and the student distribution. Ev in evleft and evright stands for extremevalue, evleft with heavy left tail and evright with heavy right tail. The first three distributions are related to the logit, probit and complementaryloglog link functions that can be specified with the LINK option of the MODEL directive. The standard deviations of the normal, logistic, extremevalue and the Student distribution with DF (>2) degrees of freedom equal 1,  $\pi/\sqrt{3}$ ,  $\pi/\sqrt{6}$  and  $\sqrt{DF/(DF-2)}$  respectively. For the student distribution with DF equal to 1 or 2 no standard deviation exists. DF for the student distribution can be fixed by option DF. If this option is unset, DF is estimated. The model for the mean can be specified by means of options INTERCEPT, CADJUST, FIXED, RANDOM, INITIAL and CONSTRAINTS, as in VCOMPONENTS and REML. Option INTERCEPT replaces CONSTANT, to avoid confusion with CONSTRAINTS, which has the first four characters in common. The setting CONSTRAINTS=none is not possible as it is in VCOMPONENTS. The default here for CONSTRAINTS is positive. ABSORB is as in VCOMPONENTS.

For ordinal data the cutpoints are unknown and have to be estimated. For grouped data cutpoints can be set by option CUTPOINTS. If cutpoints are known the dispersion of the underlying distribution is estimated.

FDISPERSION, RDISPERSION and IDISPERSION can be used to specify the linear model for the residual variance (dispersion) at the log scale, FDISPERSION for fixed effects, RDISPERSION for random effects. Only a list of factors is allowed for FDISPERSION and RDISPERSION. The scaling is such, that the dispersion for the first level of the factors in FDISPERSION or RDISPERSION is the basic dispersion, which can be set by UDISPERSION. The model can only be specified at the log scale. The random part of the model is meant to represent a relaxation of the assumption of constant dispersion and can only be specified with fixed variance components, which can be set by IDISPERSION with default value 0.1. Because for some combinations of factor levels the amount of information to estimate the specific dispersion can be very low, it is advised to use simple models for FDISPERSION only, e.g. just one factor, and to use it mainly to check constancy of dispersion. For the same reason it may be advantageous to specify RDISPERSION and not FDISPERSION, but note that fixed effects are identical to random effects with a very large component of variance. If FDISPERSION or RDISPERSION has been specified, estimates of the parameters involved, with standard errors, are reported. Also after the analysis with fixed dispersion and after the first iteration for the full model specified (including heterogeneity of dispersion), results are printed.

MAXITER, MAXCYCLE and VCONVERGENCE can be used to guide the iteration process. However, this should hardly ever be necessary, because precautions have been taken to prevent convergence problems. MAXITER and MAXCYCLE restrict the number of REML analyses and the number of cycles within each

REML analysis respectively. VCONVERGENCE sets the component of variance used for estimating the changes in the non-linear parameters (the cutpoints, DF or the parameters in FDISPERSION and/or RDISPERSION) during the iteration process.

The response can be specified in two ways: as a pointer of variates containing the frequencies in the different classes by parameter YCOUNTS, or as a variate containing the class numbers by parameter YCLASS. Note that this differs from the settings required for specifying a GLM for ordinal data with GenStat using MODEL and FIT.

## Method

The algorithm is developed from considering the relationship between the observed multinomial distribution of counts and the underlying distribution as a generalized linear mixed model with a composite link function resulting from the choice of underlying distribution. In case of a GLM iterative reweighted least squares (IRLS) can be applied to the adjusted dependent variate. Because of the equivalence of the Poisson distribution conditional on the multinomial total and the multinomial distribution, Poisson weights can be used for the frequencies. This then results in maximum likelihood estimates of the parameters. The extension from GLM to GLMM has been described in Engel and Keen (1994), Schall (1991) and as PQL in Breslow and Clayton (1993). The method replaces IRLS by iterative reweighted REML. In this case, with grouped data, the composite link function involves non-linear parameters, namely the unknown cutpoints (for ordinal data, otherwise the dispersion), the degrees of freedom of the Student distribution and parameters of the model for the dispersion. These non-linear parameters are estimated essentially by the Gauss Newton method, as described by Pregibon (1980). In this way in fact they are treated as location parameters for the observed frequencies. So all parameters are estimated simultaneously, avoiding difficulties with conditional accuracy's. This extension for ordinal data has been explained in Keen and Engel (1994). Within IRCLASS all non-linear parameters are considered as essentially random, with known variance component. They are updated in each step using the predictions of the differences with respect to the previous values. After convergence the value of the variance component (set by VCONVERGENCE) is set to 1000, which means that effectively these non-linear parameters are considered as fixed effects. The random non-linear parameters in RDISPERSION are not updated, but they are just included in the model as linearized random deviations from the assumed average value. Their use is to improve the estimates of the fixed effects and their standard errors.

The algorithm involves two or three steps. In the first step the fixed effects model including only the unknown cutpoints as non-linear parameters to be estimated, is fitted using cumulative frequencies, assuming independent binomial distributions and omitting the last class. This preliminary analysis provides initial estimates of the linear predictor and the cutpoints. In the second step the GLMM in the mean of the underlying distribution is fitted with constant dispersion to the frequency data. If a model for the dispersion has been specified, it is fitted in the third step, extending the model used in the second step with the model for the heterogeneity of dispersion.

## Action with RESTRICT

Restrictions on the response variates or the model terms are not allowed.

## Procedures Used

None.

## Similar Procedures

For ordinal data IRCLASS is an extension of a generalized linear model with the multinomial distribution. The way of extending a GLM to a GLMM is similar to procedures IRREML and GLMM, which are meant for other data types. For grouped data IRCLASS is an extension of the GenStat DISTRIBUTION directive.

CONSTRAINTS = <i>string token</i>	How to constrain each variance component (positive, fixrelative, fixabsolute); default posi
PSE = <i>string tokens</i>	Standard errors to be printed with tables of effects and means (none, differences, estimates, alldifferences, allestimates); default diff
RMETHOD = <i>string token</i>	Whether to use all the random terms, just random terms in the final stratum or both when saving RESIDUALS (final, all, both); default final. Corresponding fitted values are produced, e.g. for final the fitted values are a combination of the estimated fixed effects and predicted random effects
MAXITER = <i>scalar</i>	Maximum number of REML analyses; default 50

MAXCYCLE = <i>scalar</i>	Maximum number of iterations within each REML; default 10
DESIGN = <i>string token</i>	Whether or not the design is balanced (balanced, unbalanced); default unbalanced
CONVERGENCE = <i>scalar</i>	Constant between 0 and 1 to use as fixed value in the update between REML analyses; default 1, and adaptation to lower values after a number of iterations, if necessary
CRITERION = <i>scalar</i>	Convergence criterion; the mean relative change in the linear predictor between successive fits, expressed as a percentage; default 0.01 (%)
ZWEIGHTS = <i>string token</i>	Whether to fix weights to 1 in REML step ( <i>fix, free, no</i> ); default no
EPS = <i>scalar</i>	Value used to force the mean to keep clear from its limits; default 0.0001
CHECK = <i>string token</i>	Whether the adequacy of the variance function has to be checked ( <i>yes, no</i> ); default no
METHOD = <i>string token</i>	Indicates whether to use the standard Fisher scoring algorithm or the AI algorithm with sparse matrix methods ( <i>Fisher, AI</i> ); default AI

## Parameters

Y = <i>variates</i>	Response variates
NBINOMIAL = <i>variates</i> or <i>scalars</i>	Total numbers for DIST=binomial
ITERATIVEWEIGHTS = <i>variates</i>	To save iterative weights which are used at the lowest stratum in the final analysis
YADJUSTED = <i>variates</i>	To save the adjusted dependent variate for which the final analysis is carried out
LINEARPREDICTOR = <i>variates</i>	To save fitted values on the link scale
FITTEDVALUES = <i>pointers</i> or <i>variates</i>	To save fitted values on the original scale as specified by the RMETHOD option; pointers if RMETHOD=both and variates otherwise
RESIDUALS = <i>pointers</i> or <i>variates</i>	To save Pearson residuals on the original scale as specified by the RMETHOD option; pointers if RMETHOD=both and variates otherwise. The residuals are based on the means conditional upon the random effects, i.e. $(y-\mu)/\sqrt{w}$ , where $\mu$ is the conditional mean and $w$ is the iterative weight (if specified, prior weights are included as well)

## Description

Procedure IRREML fits a GLMM, applying iterative reweighted REML to the link adjusted dependent variate. A GLMM can be looked at in two different ways: as an extension of a linear mixed model (LMM), allowing the response variate to be non-normally distributed and specification of the LMM at another scale, or as an extension of a generalized linear model (GLM), allowing random terms to be added to the fixed terms in the linear predictor. The estimation procedure can be derived as an extension of the iterative reweighted least squares algorithm for GLMs (Schall, 1991; Engel and Keen, 1994) replacing weighted least squares by weighted REML, or by approximation of the likelihood equations by iterative use of Laplace integration (penalized quasi-likelihood; Breslow and Clayton, 1993; Engel, 1997).

The options which will be most frequently used are DISTRIBUTION and LINK to specify the distribution of the response variate and the link function, and FIXED and RANDOM to specify the fixed and random part of the model. The response variate is specified by means of the Y parameter and, if DIST=binomial, binomial totals have to be specified by means of the NBINOMIAL parameter. The other parameters allow saving of results after the model has been fitted.

Most of the options of IRREML are similar to the options of GenStat directives MODEL, VCOMPONENTS and REML. Options DISTRIBUTION, LINK, EXPONENT, DISPERSION, OFFSET and WEIGHTS originate from the MODEL directive. Note that in the output the dispersion factor is presented in the form of a residual variance together with the variance components. However, the dispersion factor is part of the conditional variance, while the variance components involve the conditional mean. The lognormal distribution is added to IRREML. For the negative binomial distribution the default LINK is logarithm, not canonical. An

extra option related to the binomial distribution is `PROBMIN`, with which a fixed lower bound for the binomial probability can be set. The binomial link function is modified accordingly.

Options `FIXED`, `ABSORB`, `CONSTANT`, `CADJUST`, `RELATIONSHIP`, `RANDOM`, `INITIAL` and `CONSTRAINTS` originate from the `VCOMPONENTS` directive. The setting `CONSTRAINTS=none` is not possible as it is in `VCOMPONENTS`. Here the default is `CONSTRAINTS=positive`. The constraint for the residual variance must not be set with `CONSTRAINTS`, but with `DISPERSION`.

Options `PRINT`, `FACTORIAL`, `PSE` and `RMETHOD` originate from the `REML` directive. The `PRINT` option is extended with the `fullmonitoring` setting, which provides more detailed information about the fitting process. Also, `RMETHOD` is extended to save two kinds of residuals and fitted values: including and excluding predictions of random parameters. However, residuals saved with `RMETHOD=all` will probably be meaningless for non Normal distributions.

Options specific to `IRREML` are `GLM`, `STARTMEAN`, `MAXITER`, `MAXCYCLE`, `DESIGN`, `CONVERGENCE`, `CRITERION`, `ZWEIGHTS`, `EPS` and `CHECK`. The `GLM` option specifies a fixed effects model to be fitted in order to obtain starting values for the iterative `REML`. `STARTMEAN` can be used to specify fitted values which are used in the first `REML` step and can reduce computing time if a second analysis is required with a slightly modified model. `MAXITER` and `MAXCYCLE` restrict the number of `REML` analyses and the number of iterations within each `REML` analysis respectively. The `CONVERGENCE` option can be set to a smaller value if convergence is a problem, `CRITERION` can be used to set the convergence criterion and `EPS` specifies how close the linear predictor is allowed to approach its limits (see the Method section). Because suitable defaults have been chosen it will usually not be necessary to specify `GLM`, `MAXITER`, `MAXCYCLE`, `CONVERGENCE`, `CRITERION` and `EPS`. Only in situations with very little information in the data they might be useful. `ZWEIGHTS` can be used to define equal weights at the link scale. `ZWEIGHTS` overrules the weights set implicitly by `DISTRIBUTION` and `LINK`. `DESIGN` can be used to perform ANOVA in balanced designs with constant weights at the link scale instead of `REML`. `CHECK` performs a check on the adequacy of the variance function. The `METHOD` option determines which algorithm to use.

`VKEEP` can be used after `IRREML` in the usual way. Residuals and fitted values from `VKEEP` are obtained with `RMETHOD=all`. The `PREDICT` directive can not be used.

## Method

First a `GLM` is fitted with the model as set by the `GLM` option, or the `FIXED` model otherwise. Then, for estimating the variance components, weighted `REML` is carried out iteratively. Weights are the usual iterative weights of a `GLM` and are functions of the estimated conditional means  $\mu$ , in which predicted random effects are included.

Numerical problems may arise if the mean  $\mu$  of an observation is not estimable, e.g. for the binomial distribution if the binomial fraction equals 0 or 1, which corresponds with plus or minus infinity for  $\text{logit}(\mu)$ . In order to avoid these problems, the linear predictor is restricted such that means remain within a distance `EPS` from their limits. A message is printed when these limits are reached.

Differences between successive fits in the iteration process are characterized by differences in the linear predictor. The mean relative change in the linear predictor, expressed as a percentage, is therefore used as convergence criterion. Convergence problems may occur if information about effects is poor, inducing large changes from one step to the next, possibly leading to a constant change between alternating estimates. This is remedied automatically, using a proportion *alfa* of the new linear predictor plus a proportion  $(1-\textit{alfa})$  of the previous linear predictor for the next step in case estimates tend to alternate. When the iteration process diverges, the iteration is restarted with a lower value for *alfa*. The `CONVERGENCE` option can be used to fix the value of *alfa*.

The extra parameter *phi* in the variance function of the negative binomial distribution  $(\mu + \textit{phi} \mu^2)$  is estimated by extending Williams' method. This involves equating Pearson's Chisquare statistic to an approximate number of degrees of freedom. These degrees of freedom are obtained by subtracting approximate degrees of freedom for the random components from the total residual degrees of freedom after fitting the fixed effects. Approximate degrees of freedom for a random term are calculated as the ratio of the sum of squared predictions of the random effects and the corresponding estimated variance component, see also Engel et al. (1995).

The CHECK option produces a plot of absolute residuals to the power 2/3 against the linear predictor. Taking absolute values of residuals allows looking at a trend in means in stead of a trend in ranges. The power 2/3 has been chosen, because the distribution of the residuals is then more symmetric.

### Action with RESTRICT

The response variates and variates and factors in GLM, FIXED, RANDOM and Y may be restricted. Restrictions on different structures must be in line. The analysis is restricted accordingly.

## LRPAIR

P.W. Goedhart

Gives (scaled) likelihood ratio tests for all pairwise differences of means from a regression or GLM

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What to print (differences, teststatistics, probabilities); default diff, test, prob
DMETHOD= <i>string token</i>	Basis of estimate of dispersion for scaled likelihood ratio statistics, if not fixed by DISPERSION option (deviance, Pearson); default as set in MODEL

### Parameters

TREATFACTOR = <i>factors</i>	Factors for which to perform tests of all pairwise differences
DIFFERENCES = <i>symmetric matrices</i>	To save pairwise differences on the linear scale (treatment means on the diagonal)
TESTSTATISTICS = <i>symmetric matrices</i>	To save the (scaled) likelihood ratio test statistics (missing values on the diagonal)
PROBABILITIES = <i>symmetric matrices</i>	To save the probabilities of the test statistics (missing values on the diagonal)

### Description

When analysing a (generalized) linear model with the regression directives FIT, ADD etc., effects of factors in the model may be assessed from an analysis of variance (or deviance) table. With the PREDICT directive tables of estimated means and their standard errors can be obtained. The LRPAIR procedure provides additional information on such tables by calculating (scaled) likelihood ratio test statistics and corresponding probabilities for tests of all pairwise differences of means. This is similar to procedure RPAIR which calculates Wald test statistics instead of (scaled) likelihood ratio statistics. LRPAIR is especially useful for models in which parameter estimates are plus or minus infinity. This can e.g. happen in Poisson and binomial GLMs when some factor categories have zero counts only. Note that for ordinary regression with the normal distribution RPAIR and LRPAIR are equivalent.

A call to LRPAIR must be preceded by fitting a (generalized) linear model. The TREATFACTOR parameter must be set to a factor for which all pairwise differences must be tested. This factor must be an additive term in the fitted model, so interactions with this factor are not allowed. In case the MODEL statement for the regression has defined multiple response variates, tests are only calculated for the first response variate.

The DMETHOD option indicates how the likelihood ratio statistics should be scaled if the DISPERSION option of the MODEL directive is not set. By default the DMETHOD setting of MODEL is used but this can be overridden by the DMETHOD option of LRPAIR.

The PRINT option controls the output. By default a symmetric matrix of pairwise differences of means is printed with the means themselves down the diagonal. With a GLM these means and their pairwise differences are always calculated on the linear scale. The corresponding pairwise test statistics and pairwise probabilities are printed by default too. The TESTSTATISTICS, PROBABILITIES and DIFFERENCES parameters can be used to save the output.

### Method

Suppose the equality of the parameters associated with levels 1 and 2 of a factor must be tested. The (scaled) likelihood ratio test is then obtained by employing the deviance of the model with the factor itself, and the deviance of the model with a modified factor in which the levels 1 and 2 have been combined. Since there are in general multiple pairwise comparisons this is done in a loop. When the DISPERSION parameter of the MODEL statement is set to a fixed value, the test statistic is the difference between the two deviances scaled by the fixed dispersion, and probabilities are calculated by means of the Chi-squared distribution. In case DISPERSION=\*, the deviance difference is scaled by the quotient of the deviance or

the Pearson statistic and the residual degrees of freedom of the full model, and the F distribution is used to calculate probabilities. Pairwise differences are obtained by means of the PREDICT directive employing default options with the exception of option setting BACKTRANSFORM=none in order to obtain means on the linear link scale.

The procedure redefines the maximal model to the fitted model by means of the TERMS directive. This is due to a limitation of GenStat. This implies that the following two sets of statements produce a fault, since the maximal model after the call to LRPAIR only has terms Rows + Treatment.

MODEL	response	MODEL	response
TERMS	Rows + Cols + Treatment	FIT	Rows + Treatment
FIT	Rows + Treatment	LRPAIR	Treatment
LRPAIR	Treatment	FIT	Rows + Cols + Treatment
FIT	Rows + Cols + Treatment		

This can be overcome by redefinition of the maximal model after the call to LRPAIR, or by repeating the MODEL statement.

### Action with RESTRICT

TREATFACTOR must not be restricted, or it must have the same restriction as the response variate.

### References

None.

### Procedures Used

SUBSET.

### Similar Procedures

Procedures RPAIR and PAIRTEST both produce a symmetric matrix of two-sided t-probabilities for tests of all pairwise differences of estimates. Procedure PPAIR displays results of tests for pairwise differences in compact diagrams.

# MATCHTARGET

*J.T.N.M. Thissen & L.C.P. Keizer*

Extracts units of a set of vectors by matching a target vector

[contents](#) [previous](#) [next](#)

## Options

<code>SORT = string token</code>	Whether the values of <code>TARGETVECTOR</code> should be sorted (yes, no); default no
<code>DIRECTION = string token</code>	Order in which to sort (ascending, descending); default ascending

## Parameters

<code>OLDVECTORS = pointers</code>	Set of vectors from which units are extracted; must be set
<code>TARGETVECTOR = variates or texts</code>	The target vector according to which units from <code>OLDVECTORS</code> are extracted; must be set
<code>NEWVECTORS = pointers</code>	Set of vectors to save the extracted units of <code>OLDVECTORS</code> ; must be set

## Description

`MATCHTARGET` extracts units of a set of vectors by matching a target vector and saves these units in a new set of vectors. `MATCHTARGET` gives control over the order of the extracted units, and is thus an alternative for the `SUBSET` procedure. The target vector specified by the `TARGETVECTOR` parameter must be a text structure or a variate with unique values. The first vector of the `OLDVECTORS` parameter must be of the same type as the `TARGETVECTOR` and must also have unique values. The other structures of `OLDVECTORS` can be factors, variates or text structures. The `NEWVECTORS` parameter saves all units of the `OLDVECTORS` structures for which the `TARGETVECTOR` equals the first vector of `OLDVECTORS`. In case an element of the target vector is not present in the first vector of `OLDVECTORS`, corresponding units in the `NEWVECTORS` are set to missing. The number of values of the `NEWVECTORS` structures is thus equal to the number of values of the `TARGETVECTOR`. The first structure of `NEWVECTORS` is always a copy of `TARGETVECTOR`.

By default the values of the `NEWVECTORS` structures are in the same order as the `TARGETVECTOR`. The `SORT` option can be used, in combination with option `DIRECTION`, to sort the `TARGETVECTOR` in ascending or descending order.

The difference with the `SUBSET` procedure is the order in which the units are saved, which is given by the `TARGETVECTOR`, and the inclusion of missing units which makes the length of the `NEWVECTORS` structures equal to the length of the `TARGETVECTOR`.

## Method

The `EQUATE` directive, with proper specifications of the options `OLDFORMAT` and `NEWFORMAT`, is used to perform the extraction.

## Action with RESTRICT

If the `TARGETVECTOR` is restricted, only the subset of values specified by the restriction will be included in the extraction. The `OLDVECTORS` structures must not be restricted.

## References

None.

## Procedures Used

`SUBSET`.

## Similar Procedures

WEAVEVECTORS weaves two sets of vectors into a new set according to the first vector of both sets. SUBSET forms vectors containing subsets of the values in other vectors. JOIN joins or merges two sets of vectors together, based on the values of sets of classifying keys.

# MOSTSIMILAR

J.T.N.M. Thissen

Displays the most similar units for each candidate unit given a set of variates

[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string token</i>	What to print (description); default description
METHOD = <i>string token</i>	Which distance metric to use (cityblock, euclidean); default cityblock
FIELDWIDTH = <i>scalar</i>	Field width in which to print the results; default 10
DECIMALS = <i>scalar</i>	Number of decimal places for printing the results; default *

## Parameters

DATA = <i>pointers</i>	Pointer to variates; must be set
UNITS = <i>texts</i>	Text structure to identify the units; must be set
YARDSTICK = <i>variates</i>	Yardsticks of the variates in DATA; must be set
GROUPS = <i>factors</i>	Factor with 2 levels: level 1 for candidate units, level 2 for reference units; by default all units are candidate units
SINGULARUNITS = <i>texts</i>	To save the singular units

## Description

Procedure MOSTSIMILAR can be used to display the most similar units for each candidate unit given a set of variates as specified by the DATA pointer. The most similar units with METHOD=cityblock are the units with all absolute differences less than or equal to the corresponding value of the YARDSTICK parameter. With METHOD=euclidean the most similar units are the units within an ellipsoid around the candidate unit; the YARDSTICK parameter then defines the lengths of the axes of the ellipsoid. The length of the YARDSTICK variate must thus be equal to the number of DATA variates. The units must be identified by a text structure as specified by the UNITS parameter. The GROUPS parameter can be used to subdivide the units into candidate and reference units. The GROUPS factor must have the levels 1 and 2; level 1 for the candidate units and level 2 for the reference units. If the GROUPS factor is not set all units are considered candidate units. The set of candidate units that don't have most similar units can be saved by the SINGULARUNITS parameter.

The PRINT option can be used to omit the description, and the FIELDWIDTH and DECIMALS options both operate in a straightforward way. If the setting of FIELDWIDTH is smaller than the longest structure name, the length of the longest structure name plus 1 is taken as field width. If not set the default value is 10. If the DECIMALS option is not set the number of decimals is determined by application of the DECIMALS procedure to the YARDSTICK variate.

## Method

MOSTSIMILAR uses simple calculations.

## Action with RESTRICT

Restrictions are not allowed.

## References

None.

## Procedures Used

DECIMALS, SREPLACE, RENAMEP POINTER and VEQUATE.

## Similar Procedures

BKEY constructs an identification tree.

## OCATTRIBUTES

J.T.N.M. Thissen

Calculates operating characteristic curves for single and multiple acceptance sampling plans for attributes

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	What to print (probabilities); default probabilities
PLOT = <i>string token</i>	What to plot (occurve); default occurve
TITLE = <i>text</i>	General title for plot; default *
DISTRIBUTION = <i>string token</i>	Type of distribution (binomial, hypergeometric, poisson); default binomial
MAXPERCENTAGE = <i>scalar</i>	Maximum percentage of defectives for which acceptance probabilities are calculated; default 30
STEPLENGTH = <i>scalar</i>	Steplength between the percentages defectives for which acceptance probabilities are calculated; default 1
POPULATIONSIZE = <i>scalar</i>	Population size for DISTRIBUTION=hypergeometric; default 1000

### Parameters

SAMPLESIZE = <i>scalars</i> or <i>variates</i>	Size of the sample(s); must be set
ACCEPTANCENUMBER = <i>scalars</i> or <i>variates</i>	Acceptance number(s); must be set
REJECTIONNUMBER = <i>scalars</i> or <i>variates</i>	Rejection number(s); must be set
PROBABILITYACCEPTANCE = <i>variates</i>	Saves the probabilities of acceptance
PERCENTAGEDEFECTIVE = <i>variates</i>	Saves the percentages defectives
AVERAGESAMPLENUMBER = <i>variates</i>	Saves the average sample numbers

### Description

OCATTRIBUTES calculates operating characteristic (OC) curves for single and multiple acceptance sampling plans for attributes. The sampling plan is specified by the parameters SAMPLESIZE, ACCEPTANCENUMBER and REJECTIONNUMBER. The length of these parameters determines the number of stages of the plan. For a single sampling plan these parameters can also be set to scalars in which case REJECTIONNUMBER can be left unset. A negative ACCEPTANCENUMBER in stages before the last stage in a multiple sampling plan defines that the decision at the corresponding stage can only be to proceed or to reject. For the last stage in a multiple sampling plan the rejection number must be equal to the corresponding acceptance number + 1.

The type of distribution can be specified by the DISTRIBUTION option. The hypergeometric distribution is not available for multiple sampling plans. If DISTRIBUTION=hypergeometric the POPULATIONSIZE option must be set. The MAXPERCENTAGE option specifies the maximum percentage of defectives for which to calculate the probabilities of acceptance. For the binomial and poisson distribution, the step length between 0 and MAXPERCENTAGE can be supplied by the STEPLENGTH option.

By default OCATTRIBUTES plots an OC curve, but you can set PLOT=\* to suppress this. The TITLE option allows you to supply a title for the graph. Also, unless you set option PRINT=\*, OCATTRIBUTES prints the calculated acceptance probabilities and the average number of sample sizes.

The probabilities of acceptance can be saved by the PROBABILITYACCEPTANCE parameter, the percentages defectives by the PERCENTAGEDEFECTIVE parameter and the average sample numbers by the AVERAGESAMPLENUMBER parameter.

## Method

The probability functions of GenStat are used to calculate the acceptance probabilities. For not too small sample sizes the Poisson distribution is a good approximation of the Binomial distribution with mean parameter (Samplesize \* PercentageDefective). If the ratio between sample size and population size is small, the Binomial distribution is a good approximation of the Hypergeometric distribution.

## Action with RESTRICT

Restrictions are not allowed.

## OCPLAN

J.T.N.M. Thissen

Finds a single acceptance sampling plan for attributes given two points on an OC curve

[contents](#) [previous](#) [next](#)

### Options

PRINT = *string token*                      What to print (plan); default plan

### Parameters

PERCENTAGEDEFECTIVE = *variates*                      Variate with two percentages defectives; default !(1,10)

PROBABILITYACCEPTANCE = *variates*                      Variate with two probabilities of acceptance corresponding to the PERCENTAGEDEFECTIVE variate; default !(0.95,0.05)

SAMPLESIZE = *scalars*                      Saves the sample size

ACCEPTANCENUMBER = *variates*                      Saves the acceptance number

### Description

OCPLAN finds a single acceptance sampling plan for attributes given two points of an operating characteristic (OC) curve. The two points are specified by the PERCENTAGEDEFECTIVE and PROBABILITYACCEPTANCE variates. The length of both variates is 2 with default settings PERCENTAGEDEFECTIVE=!(1,10) and PROBABILITYACCEPTANCE=!(0.95,0.05). The first percentage defective should be smaller than the second, whereas the first acceptance probability should at least 0.50 be greater than the second.

The sample size of the found single sampling plan can be saved by the SAMPLESIZE parameter and the acceptance number by the ACCEPTANCENUMBER parameter. The PRINT option prints the plan unless you set option PRINT=\*

### Method

The calculation is done using percentage points of a Chi-squared distribution. This means that the calculation, apart from a rounding error to an integer of the SAMPLESIZE, is exact if the probability distribution of the number of defectives in a sample is Poisson.

### Action with RESTRICT

Restrictions are ignored.

```

## PER2MUTE

P.W. Goedhart

Forms all possible permutations of a set of values

[contents](#) [previous](#) [next](#)

### Options

MAXPERMUTATIONS = <i>scalar</i>	The maximum number of permutations that should be stored; default 10000
SEED = <i>scalar</i>	Seed to generate the random numbers; default 0 continues an existing sequence or initialises the sequence automatically if no random numbers have been generated in this job
NOMESSAGE = <i>string token</i>	Which messages to suppress (warning); default *

### Parameters

STRUCTURE = <i>identifiers</i>	Numerical structure (variate, table, matrix, symmetricmatrix, diagonalmatrix) whose values must be permuted
PERMUTATIONS = <i>pointers</i>	Pointer to a set of variates storing the permutations; the length of each variate equals the number of values in STRUCTURE
NPERMUTATIONS = <i>scalars</i>	To save the number of permutations

### Description

PER2MUTE forms all the permutations of the values in the STRUCTURE parameter. This procedure uses an external C# program. The input variate may contain multiple values. For example, the permutations of the numbers (1, 1, 2, 2) are as follows (1, 1, 2, 2), (1, 2, 1, 2), (1, 2, 2, 1), (2, 1, 1, 2), (2, 1, 2, 1) and (2, 2, 1, 1). The permutations are saved, as a set of variates each of length equal to the number of values in STRUCTURE, in a pointer supplied by the PERMUTATIONS parameter. The number of permutations can be saved by setting the NPERMUTATIONS parameter. The number of decimals of the STRUCTURE parameter is copied to the permutation variates.

If the number of permutations is larger than the setting of the MAXPERMUTATIONS option, but smaller than or equal to 40.000.000, a random subset of size MAXPERMUTATIONS is saved. If the number of permutations is larger than 40.000.000 the external C# takes too long. In that case the RANDOMIZE directive is used to return random permutations which are not guaranteed to be unique, i.e. duplicate permutations are possible. The SEED option can be set to initialise the random-number generator, if applicable, hence giving identical results if the procedure is called again with the same options. If SEED is not set, generation will continue from the previous sequence in the program, or, if this is the first generation, the generator will be initialised by CALCULATE. The NOMESSAGE option can be used to suppress warning messages.

### Method

When the number of permutation is smaller than or equal to 40.000.000 the values are passed to an external C# .NET Framework 3.5 program by using the SUSPEND directive. The C# program employs a translation of Applied Statistics Algorithm AS 179 (Berry, 1982) to calculate the permutations. The algorithm takes account of multiple values. When the number of permutations is larger than 40.000.000 the values are repeatedly randomized using the RANDOMIZE directive.

### Action with RESTRICT

If the STRUCTURE parameter is restricted, only the values in the restriction set are used to form the permutations. The length of the permutation variates will equal the length of the restricted STRUCTURE.

### References

Berry, J.B. (1982). Algorithm AS 179: Enumeration of All Permutations of Multi-Sets with Fixed Repetition Numbers. *Applied Statistics*, **31**, 169-173.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

PERMUTE forms all possible permutations of the integers 1...n.

## Example

```
CAPTION 'PER2MUTE example' ; STYLE=meta
VARIATE [VALUES=1, 1, 2, 2, 3] v1 ; DECIMALS=0
VARIATE [VALUES=1.1, 2.2, 3.3, 4.4] v2 ; DECIMALS=1
PER2MUTE v1,v2 ; p1,p2
PRINT p1[] ; FIELD=8
PRINT p2[] ; FIELD=8
```

## PPAIR

P.W. Goedhart, H. van der Voet &amp; D.C. van der Werf

Displays results of t-tests for pairwise differences in compact diagrams

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What to print ( <i>items</i> , <i>groups</i> ); default <i>groups</i>
PROBABILITY = <i>scalar</i> or <i>symmetric matrix</i>	Level of significance for t-tests of all pairwise comparisons, default 0.05
SORT = <i>string token</i>	Whether the diagrams are sorted according to the values of (the diagonal of) DIFFERENCES ( <i>yes</i> , <i>no</i> ); default <i>no</i>
DIRECTION = <i>string token</i>	Order in which to sort when SORT= <i>yes</i> ( <i>ascending</i> , <i>descending</i> ); default <i>ascending</i>
COLUMNS = <i>string token</i>	Whether the letters in the groups diagram should be printed in columns with added dots for increased readability or not ( <i>yes</i> , <i>no</i> ); default <i>yes</i>
SPACES = <i>string token</i>	Whether to display additional spaces for increased readability or not ( <i>yes</i> , <i>no</i> ); default <i>yes</i>
NOMESSAGE = <i>string token</i>	Whether to hide a warning message when there are significant differences within groups with a common letter in the groups diagram ( <i>yes</i> , <i>no</i> ); default <i>no</i>

### Parameters

TPROBABILITIES = <i>symmetric matrices</i>	Probabilities of t-tests of pairwise comparisons; this parameter must be set
DIFFERENCES = <i>symmetric matrices, variates</i> or <i>tables</i>	Defines the ordering of TPROBABILITIES for the <i>groups</i> diagram; must be set for a <i>groups</i> diagram
LABELS = <i>texts</i>	Text vector labelling the output; if unset the row labels of TPROBABILITIES and the diagonal of DIFFERENCES are used
DIAGRAMS = <i>pointers</i>	Pointer to save text structures containing the diagrams

### Description

Procedures RPAIR and PAIRTEST produce a symmetric matrix of two-sided t-probabilities for tests of all pairwise differences. Procedure PPAIR displays this matrix at a specified level of significance in two compact diagrams. This is especially useful when the number of estimates is large.

Input to PPAIR is a symmetric matrix TPROBABILITIES containing probabilities of the set of pairwise comparisons. The level of significance can be set by the PROBABILITY option. A common level is specified by a scalar, while a symmetric matrix specifies a level for each comparison separately (which may be useful for some multiple comparison methods). Output is labelled by the row labels of TPROBABILITIES. If the DIFFERENCES parameter is set to a symmetric matrix, the diagonal of this matrix is printed alongside these labels. This is especially useful if DIFFERENCES is saved by RPAIR or PAIRTEST because it then contains the estimates on the diagonal. DIFFERENCES can also be set to a variate or table. Alternatively the output can be labelled by specifying parameter LABELS.

The PRINT option controls which diagram is printed. PRINT=*items* produces a diagram which should be read line by line. Each item (represented by a letter) is followed by those items (again represented by letters) not significantly different from that item. When there are more than 52 items, letters are repeated. PRINT=*groups* produces a diagram in which items followed by a common letter are not significantly different. Such items are said to form a homogeneous group. This is similar to common underlining of items with non-significantly different estimates. In constructing this diagram the philosophy of multistage testing is followed, see the Methods section. The SORT option controls whether the printed and saved diagrams are sorted according to the values of (the diagonal of) DIFFERENCES. The DIRECTION option defines the sorting order. The COLUMNS option controls whether the letters in the groups diagram are printed in columns with added dots for increased readability or not. The SPACES option controls whether additional spaces are printed for increased readability or whether the diagram should be as tight as possible.

The NOMESSAGE option can be used to hide a warning message when there are significant differences within groups with a common letter in the groups diagram. Diagrams can be saved by means of the DIAGRAMS parameter.

## Method

The construction of the diagram for PRINT=groups is as follows. First the matrix of TPROBABILITIES is sorted according to the values of (the diagonal of) DIFFERENCES. The difference between the first and last item of the complete set of  $n$  items is then checked for significance. Next the first and last item of all subsets of  $n-1$  consecutive items are checked, followed by all subsets of  $n-2$  items, and so on. If non-significance is found between the first and last item of a subset, all items of the subset are said to form a homogeneous group and they receive the same letter. Clearly this only makes sense when the TPROBABILITIES are sorted according to the estimates. The diagram only consists of homogeneous groups which are not a part of a larger group.

It is obvious that items in a homogeneous group can be significantly different. This is not displayed in the diagram, although a message is printed if this occurs unless otherwise requested by the NOMESSAGE option. If there are no significant differences within homogeneous groups, both diagrams essentially contain the same information; PRINT=groups then gives a more concise representation.

## Action with RESTRICT

Restrictions on DIFFERENCES and LABELS are ignored.

## References

None.

## Procedures Used

DECIMALS determines the number of decimal places of PROBABILITY if this is not set. SREPLACE.

## Similar Procedures

Procedures RPAIR, LRPAIR and PAIRTEST produce a symmetric matrix of two-sided t-probabilities for tests of all pairwise differences of estimates.

## QDIRECTORY

P.W. Goedhart

Returns a directory selected by means of a directory browse dialog box on screen

[contents](#) [previous](#) [next](#)

### Options

TITLE = <i>text</i>	Single-valued text structure specifying the title of the directory browse dialog box; must be set
ROOTDIRECTORY = <i>text</i>	Single-valued text structure which specifies the directory under which the user can browse for directories. The user will not be able to browse above this level. By default the entire file system (all drives, directories, and network shares) can be browsed. Note that a setting of C: is ignored, while C:/ or C:\ is not; default *
STARTDIRECTORY = <i>text</i>	Single-valued text structure specifying the directory which will be selected by default when the dialog box is initially displayed; default *
NEWFOLDERBUTTON = <i>string token</i>	Whether to display a "New Folder" button in the browse dialog box (yes, no). This option is not available for all Windows versions; default no

### Parameters

DIRECTORY = <i>text</i>	Saves the selected directory; must be set
-------------------------	---

### Description

Procedure QDIRECTORY can be used to return a directory selected by means of a directory browse dialog box on screen. This procedure uses an external C# program. The title of the dialog box must be specified by the TITLE parameter. The ROOTDIRECTORY and STARTDIRECTORY options determine the initial state of the dialog box. In case ROOTDIRECTORY is set the user will not be able to browse above the specified directory. In case the STARTDIRECTORY is set the initial directory will be set to that directory, but the full directory tree can be browsed. Note that when ROOTDIRECTORY is set, the setting of STARTDIRECTORY will be ignored. Additionally a "New Folder" button can be displayed by setting the NEWFOLDERBUTTON option to no. The selected directory is saved by means of the DIRECTORY parameter.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

### Similar Procedures

DIRLIST provides details about (wildcarded) files in a specified directory. QFILENAME returns filenames selected by means of a file open dialog box on screen.

**Example**

```
CAPTION      'QDIRECTORY example' ; STYLE=meta
QDIRECTORY [TITLE='Example 1'] directory
PRINT       [IPRINT=*] directory ; SKIP=2
DIRECTORY [TITLE='Example 2' ; ROOTDIRECTORY='C:/Windows'] directory
PRINT       [IPRINT=*] directory ; SKIP=2
QDIRECTORY [TITLE='Example 3' ; STARTDIRECTORY='C:/Windows'] directory
PRINT       [IPRINT=*] directory ; SKIP=2
```

# QENQUIRE

P.W. Goedhart

Provides details about files and can be used to open or close files

[contents](#) [previous](#) [next](#)

## Options

ACTION = *string token* Action to take for the specified file (open, close); default \*

## Parameters

FILENAME = <i>texts</i>	Full name of the file specified as a single valued text
EXIST = <i>scalars</i>	To indicate whether currently exist (0=does not exist, 1=exist)
ACCESS = <i>texts</i>	To indicate whether the file is available for read and/or write, saved as a single text equal to either none or readonly or writeonly or both.
SUCCESS = <i>scalars</i>	Whether the specified action was executed successfully (1) or not (0)

## Description

Procedure QENQUIRE provides details about existence and access of files, and can also be used to open or close files. The FILENAME parameter must be set to an external file. The existence of the file can be saved by means of the EXIST parameter, and the type of access can be saved by means of the ACCESS parameter. The latter can be either “none”, “readonly”, “writeonly” or “both”. In case the file does not exist, ACCESS is set to “none”.

QENQUIRE can also be used to open or close files. Opening a file only works in case the file has an application associated with it, or when the file is an executable itself. Closing a file should be avoided as this unconditionally kills the associated application without saving any changes. Closing a file performs a loop over all open applications. An application is closed when its main title contains, as a word, either the filename with directory or the filename without the directory. In case FILENAME is set to an executable the filename without extension is used to check against. Note that the string comparison is case sensitive. The unconditional kill of an application might have undesirable side effects. For example, closing an Excel file by QENQUIRE and re-opening it again might result in an attempt by Excel to recover a previous version of the Excel file.

## Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program. The C# code for ACTION=close is as follows:

```
Process[] processlist = Process.GetProcesses();
foreach (Process proc in processlist) {
    string[] words = proc.MainWindowTitle.Trim().Split(' ');
    foreach (string word in words) { if ((word == path) || (word == filename)) proc.Kill(); }
}
```

## Action with RESTRICT

Not relevant.

## References

None.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

None.

**Example**

```
CAPTION 'QENQUIRE example' ; STYLE=meta
BIOMETRIS [GENDIRECTORY=gendir]
CONCATENA [GenStat] gendir, 'bin\\GenStat.exe'
CONCATENA [XlsFile] gendir, 'Data\\Bacteria.xls'
CONCATENA [NoFile] gendir, 'NoFile.aaa'
FOR file=GenStat, XlsFile, NoFile
  QENQUIRE file ; EXIST=exist ; ACCESS=access
  PRINT exist,access,file ; FIELD=6,11,* ; SKIP=0,0,4 ; JUST=2(right),left
ENDFOR
QENQUIRE [ACTION=open] XlsFile
```

## QFILENAME

P.W. Goedhart

Returns filename(s) selected by means of a file open dialog box on screen

[contents](#) [previous](#) [next](#)

### Options

TITLE = <i>text</i>	Single-valued text structure specifying the title of the file open box; must be set
DIRECTORY = <i>text</i>	Single-valued text which specifies the default directory for the filename; default *, i.e. the current working directory
DEFAULTFILE = <i>text</i>	Single-valued text which specifies the default filename or file mask; default '*.*', i.e. all files in the selected directory
FILETYPES = <i>texts</i>	File type selection definitions as used in the "Files of type" section of the file open box. Each text must be single-valued and must contain a single description and a single file mask separated by a " " symbol; default 'All Files (*.*) *.*'
MULTISELECT = <i>string token</i>	Whether multiple files can be selected (yes, no); default no
STYLE = <i>string token</i>	Visual style of file open dialog to use (old, new); default new
SAVEDIRECTORY = <i>text</i>	Saves the directory of the selected file(s)
EXISTSDIRECTORY = <i>scalar</i>	Saves whether the default DIRECTORY exists (1) or not (0)

### Parameters

FILENAME = <i>texts</i>	Saves the name of the selected file including the full path
SURNAME = <i>texts</i>	Saves the surname of the selected file, i.e. the name excluding the path, the period and the extension
EXTENSION = <i>texts</i>	Saves the extension of the selected file, excluding the leading period
SELECTED = <i>scalars</i>	Scalar to save the number of selected files

### Description

Procedure QFILENAME can be used to return filename(s) selected by means of a file open dialog box on screen. This procedure uses an external C# program. The option MULTISELECT determines whether single or multiple files can be selected; the default setting no enables selection of a single file. The title of the dialog box must be specified by the TITLE parameter. The default filename, which may be wild-carded, and the default directory can be set by means of the DEFAULTFILE and DIRECTORY options respectively. File type selection definitions, as highlighted in the "Files of type" section of the file open box, can be specified by means of the FILETYPES option. This option can be set to several single-valued texts, each of which must contain a single description and a single file mask separated by a "|" symbol. An illustration of the FILETYPES option is given in the example program. In case DEFAULTFILE is not defined as the first setting of the FILETYPES option, DEFAULTFILE is added as an extra file type. The visual style of the file dialog can be set by the STYLE option.

The full name, including the path, of the selected filename(s) can be saved by means of the FILENAME parameter. Parts of the filename(s) can be saved by means of parameters SURNAME and EXTENSION, and the directory of the selected file(s) can be saved by means of the option SAVEDIRECTORY. The SELECTED parameter saves the number of selected files. If no file is selected the FILENAME, SURNAME and EXTENSION parameters and the SAVEDIRECTORY option are set to an empty string ''. The EXISTSDIRECTORY option saves whether the default directory, as specified by the DIRECTORY option, exists (1) or not (0).

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

## Action with RESTRICT

Output structures are redefined in the procedure and so restrictions on them are ignored.

## References

None.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

DIRLIST provides details about (wildcarded) files in a specified directory. SFILENAME forms sub-strings of names of files opened by GenStat. QDIRECTORY returns a directory selected by means of a directory browse dialog box on screen.

## Example

```
CAPTION 'QFILENAME example' ; STYLE=meta
TEXT filetype[1] ; 'GenStat (*.g*)|*.g*'
TEXT filetype[2] ; 'Data (*.dat)|*.dat'
TEXT filetype[3] ; 'All Files (*.*)|*.*'
QFILENAME [TITLE='Example of QFILENAME' ; FILETYPE=filetype[] ; \
          DEFAULT='*.g*'] filename ; surname ; extension ; selected
IF selected
  PRINT [ORIENTATION=across] filename, surname, extension ; \
        JUSTIFICATION=left ; SKIP=3
ENDIF
```

## QMESSAGE

P.W. Goedhart &amp; L.C.P. Keizer

Displays a message on screen

[contents](#) [previous](#) [next](#)

### Options

TITLE = <i>text</i>	Single-valued text structure specifying the title of the message screen; must be set
MESSAGE = <i>text</i>	Text structure specifying the message; default *
ICON = <i>string token</i>	Displays an extra icon along with the message (none, question, error, warning, information); default none
SECONDS = <i>scalar</i>	Number of seconds to display the message. For negative or zero values of SECONDS, the message will be displayed until the user responds by selecting the OK button of the message; default 0
CONTINUE = <i>string token</i>	Whether to continue execution of GenStat without waiting for the disappearance of the displayed message (yes, no); default no
DELETEPREVIOUS = <i>string token</i>	Whether to delete the previous message with the same title (yes, no); default yes

### Parameters

None.

### Description

Procedure QMESSAGE can be used to display a message box on screen. This procedure uses an external C# program. The title of the message box must be specified by the TITLE option, while the MESSAGE option can be used to display an additional message. The special strings @hrt and @tab in the MESSAGE option are translated into hard returns and tabs respectively. Note that separate lines in the MESSAGE option are displayed without hard returns unless the special string @hrt is used. However a line with spaces only is displayed as an empty line in the message box. An extra icon can be displayed along the message by employing the ICON option.

The SECONDS option can be used to specify the number of seconds the message will be displayed on screen, with a maximum of 3600 seconds. For negative or zero values of SECONDS, the message will be displayed until the user responds by selecting the OK button of the message.

The CONTINUE option can be used to force GenStat to wait for the disappearance of the message. The DELETEPREVIOUS option enables automatic deletion of any windows with the same setting of the TITLE option.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

Restrictions on the MESSAGE option are ignored.

### References

None.

### Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

QDIRECTORY returns a directory selected by means of a directory browse dialog box on screen. QFILENAME returns filename(s) selected by means of a file open dialog box on screen. QPICKLIST can be used to pick one or more items from a list presented on screen. QSTOPWATCH can be used to display timing information. QTEXT can be used to obtain string(s) of a text structure from screen. QYESNO can be used to choose between alternatives Yes, No and Cancel on screen.

## Example

```
CAPTION 'QMESSAGE example' ; STYLE=meta
QMESSAGE [TITLE='Example 1 of QMESSAGE' ; \
MESSAGE=!t('You can use formatting characters in the message:', \
 '@hrt@hrt1.@tabFirst item@hrt2.@tabSecond item')]
QMESSAGE [TITLE='Example 2 of QMESSAGE' ; ICON=information ; \
MESSAGE='Wait for 5 seconds ...' ; SECONDS=5 ; CONTINUE=yes]
```

## QPICKLIST

P.W. Goedhart &amp; L.C.P. Keizer

Can be used to pick one or more items from a list presented on screen

[contents](#) [previous](#) [next](#)

### Options

TITLE = <i>text</i>	Single-valued text structure specifying the title of the screen box; must be set
MESSAGE = <i>text</i>	Text structure specifying a message to display; default *
SELECT = <i>string token</i>	Whether it is possible to pick single or multiple items from the list ( <i>single</i> , <i>multiple</i> ); default <i>multiple</i>
SORT = <i>string token</i>	Whether to display an alphabetic list or not ( <i>yes</i> , <i>no</i> ); default <i>no</i>
DIRECTION = <i>string token</i>	Order in which to sort ( <i>ascending</i> , <i>descending</i> ); default <i>ascending</i>
WIDTH = <i>scalar</i>	Width of box for list of items; default 200
FONT = <i>string token</i>	Font to use for display ( <i>arial</i> , <i>consolas</i> , <i>courier</i> , <i>helvetica</i> , <i>lucida</i> , <i>microsoft</i> , <i>tahoma</i> , <i>times</i> , <i>verdana</i> ); default <i>microsoft</i>
SIZE = <i>scalar</i>	Size of font for display; default 8.25

### Parameters

LIST = <i>texts</i>	Text structure with the items which can be picked; must be set
SELECTED = <i>texts</i>	Saves selected items from the LIST parameter; must be set
VSELECTED = <i>variates</i>	Saves a variate of the same length as the LIST parameter with elements 1 (selected) or 0 (not selected)

### Description

Procedure QPICKLIST can be used to present a list of items on screen from which one or more items can be selected. This procedure uses an external C# program. The items must be specified by the LIST parameter, and the selected strings are returned by means of the SELECTED parameter. Additionally the VSELECTED parameter can be used to save a variate of the same length as the LIST parameter with elements 1 and 0, indicating whether an item is chosen (1) or not (0). The strings of the LIST parameter must be unique, i.e. duplication of strings is not allowed. Option SELECT can be used to limit the selection to one item (*single*) or to allow multiple selection (*multiple*). The SORT option specifies whether the list should be sorted or not. The DIRECTION option controls whether the ordering is into ascending or descending order; by default DIRECTION=*ascending*.

The title of the message box must be specified by the TITLE option, while the MESSAGE option can be used to display an additional message. The special string @hrt in the MESSAGE option is translated into a hard return. Note that separate lines in the MESSAGE option are displayed without hard returns unless the special string @hrt is used. However a line with spaces only is displayed as an empty line. The WIDTH, FONT and SIZE options can be used to modify the display on screen.

After selecting items, you can proceed by using the Enter key or by pressing the OK button. Alternatively you can use the "Cancel" button, in which case no items are selected; the SELECTED parameter will be set to a single-values text with the value ' ' (an empty string).

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

Restrictions on the MESSAGE option are ignored. The LIST parameter should not be restricted.

## References

None.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

QDIRECTORY returns a directory selected by means of a directory browse dialog box on screen. QFILENAME returns a filename selected by means of a file open box on screen. QMESSAGE displays a message on screen. QSTOPWATCH can be used to display timing information. QTEXT can be used to obtain string(s) of a text structure from screen. QYESNO can be used to choose between alternatives Yes, No and Cancel on screen.

## Example

```
CAPTION 'QPICKLIST example' ; STYLE=meta
TEXT [VALUES=Blue, Green, Red, Yellow, Purple] list
QPICKLIST [TITLE='Example of QPICKLIST' ; MESSAGE='Pick some colours ...' ; \
SORT=yes ; SELECT=multiple] list ; select ; vselect
PRINT list, vselect ; FIELD=12
PRINT select ; FIELD=12
```

## QREGISTRY

P.W. Goedhart

Can be used to retrieve registry keys from the registry

[contents](#) [previous](#) [next](#)

### Options

REGISTRY = <i>string token</i>	Whether to retrieve information from the 32-bit or the 64-bit registry (bit32, bit64); default bit32
HANDLE = <i>string token</i>	From which part of the registry information must be retrieved (machine, classes, current, users, config); default machine

### Parameters

MAINKEY = <i>texts</i>	Specifies the main key from which information must be retrieved; must be set
KEY = <i>texts</i>	Specifies the key from which information must be retrieved; must be set
VALUES = <i>texts</i>	Saves the value for each key; must be set

### Description

Procedure QREGISTRY can be used to retrieve registry keys. This procedure uses an external C# program. Options REGISTRY and HANDLE specify the main part of the registry from which information must be retrieved. The settings of the HANDLE option refer to the following parts of the registry

machine	HKEY_LOCAL_MACHINE
classes	HKEY_CLASSES_ROOT
current	HKEY_CURRENT_USER
users	HKEY_USERS
config	HKEY_CURRENT_CONFIG

The MAINKEY and KEY parameters further specify the subsections and keys that should be retrieved. The VALUES parameter saves the values of those keys. In case the main key or the key itself is not found, the values '\*MAINKEY not found' or '\*KEY not found' are returned.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

The MAINKEY and KEY parameters should not be restricted.

### References

None.

### Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

### Similar Procedures

None.

**Example**

```
CAPTION 'QREGISTRY example retrieves GenStat executable' ; STYLE=meta

# QSTOPWATCH

P.W. Goedhart

Can be used to display timing information

[contents](#) [previous](#) [next](#)

## Options

<code>PRINT = string tokens</code>	Where to print timing information (output, screen); default output, screen
<code>NUMBER = scalar</code>	Specifies which of 10 stopwatches to use, must be set to an integer in the interval [0,9]; default 0
<code>MODE = string token</code>	What to do with the stopwatch (start, continue, stop); default continue, or start when the stopwatch is first used
<code>NTIMES = scalar</code>	To display timing information specific to a FOR-loop: number of times the loop is executed; default *
<code>INDEX = scalar</code>	To display timing information specific to a FOR-loop: index of the loop that is being executed; default *
<code>TITLE = text</code>	Single-valued text structure specifying the title of the message screen; default *
<code>MESSAGE = text</code>	Text structure specifying the extra message; default *
<code>SAVE = pointer</code>	Pointer to save the various elements which are displayed

## Parameters

None.

## Description

Procedure QSTOPWATCH can be used to display timing information. The PRINT option determines whether timing information is displayed in the output file or in a message box on screen. The latter uses the QMESSAGE procedure and thus an external C# program. By specifying the NUMBER option, a total number of 10 different stopwatches is available. The MODE option determines whether a stopwatch is started, continued or stopped. Default is to continue the current stopwatch, or to start the stopwatch when it is called the first time.

Setting MODE=start will print or display the starting time. MODE=continue will print or display the time elapsed since the stopwatch was started. MODE=stop will print the time elapsed since the stopwatch was started, and will remove any timing messages from screen. When NTIMES and INDEX are specified in a FOR-loop, the index of the current loop is displayed, and also the time elapsed and an estimate of the remaining time necessary to finish the loop. The latter assumes that the stopwatch was started just before the FOR-loop was started, and that each loop takes the same amount of time. The MESSAGE option is always displayed in the message box, but only printed to output when NTIMES or INDEX are not set. The TITLE option can be used to specify the title of the message screen; this only takes effect when a stopwatch is started. The SAVE option can be used to save the starting time of the stopwatch, the elapsed time, the elapsed number of seconds and, for use in a FOR-loop, the index of the current loop and an estimate for the time remaining to finish the loop.

## Method

The timing functions of GenStat are used. The WORKSPACE directive is employed to store timing information between successive calls to QSTOPWATCH. The message box is displayed by the QMESSAGE procedure which activates an external C# program by means of the SUSPEND directive.

## Action with RESTRICT

Restriction on the MESSAGE parameter will be ignored.

## References

None.

## Procedures Used

QSTOPWATCH calls the subsidiary procedure %QSTOPWATCHHLP which converts the result of the NOW function to text structures containing the date and time. QMESSAGE displays the message on screen.

## Similar Procedures

None.

## Example

```
CAPTION      'QSTOPWATCH example' ; STYLE=meta
QSTOPWATCH [PRINT=* ; MODE=start ; NUMBER=1 ; MESSAGE='Overall timing']
SCALAR      ntimes, nmessage ; (5,1)*20000
QSTOPWATCH [MODE=start ; TITLE='Timing of loop']
FOR [NTIMES=ntimes ; INDEX=ii]
  IF (.NOT.MODULO(ii ; nmessage))
    QSTOPWATCH [INDEX=ii ; NTIMES=ntimes]
  ENDIF
ENDFOR
QSTOPWATCH [MODE=stop]
QSTOPWATCH [NUMBER=1 ; MESSAGE='Elapsed time since program was started']
```

## QTEXT

P.W. Goedhart &amp; L.C.P. Keizer

Can be used to obtain string(s) of a text structure from screen

[contents](#) [previous](#) [next](#)

### Options

TITLE = <i>text</i>	Single-valued text structure specifying the title of the screen box; must be set
MESSAGE = <i>text</i>	Text structure specifying a message to display; default *
DEFAULT = <i>text</i>	Default response; default *
NTIMES = <i>scalar</i>	The number of times an input string is prompted for; default 1
CASE = <i>string token</i>	Case to use for letters (given, lower, upper, changed, title); default given leaves the case of each letter as given on screen
WIDTH = <i>scalar</i>	Width of box for input of strings which must be set to an integer in the interval [200,1000]; default 200
FONT = <i>string token</i>	Font to use for display (arial, consolas, courier, helvetica, lucida, microsoft, tahoma, times, verdana); default microsoft
SIZE = <i>scalar</i>	Size of font for display; default 8.25

### Parameters

TEXT = <i>texts</i>	Text structure to save the response(s); must be set
CHECK = <i>scalars</i>	Scalar to save whether TEXT has at least one value (1) or whether it has only missing values (0)
VCHECK = <i>variates</i>	Saves a variate of the same length as the TEXT parameter with elements 1 (string present) or 0 (string missing)

### Description

Procedure QTEXT can be used to obtain string(s) of the TEXT parameter from screen. This procedure uses an external C# program. The NTIMES option specifies the number of strings which should be obtained from screen. If NTIMES is greater than 1, the strings of TEXT are obtained by repeatedly displaying a screen box until the text structure is fully filled, or until the Cancel button is pressed. The CHECK parameter saves whether the TEXT parameter has at least one value (1) or only missing values (0). The VCHECK parameter saves whether corresponding strings in the TEXT parameter are present (1) or not (0). In case no string is typed on screen, e.g. when just the OK button is pressed, the corresponding element of TEXT and VCHECK is set to missing and 0 respectively.

The DEFAULT option can be used to set a default response; this can be set to a single-valued text or to a text structure with number of values equal to the setting of the NTIMES option. The CASE option can be used to change the case of the saved text. The title setting of CASE changes the case of all letters to lowercase, except the first letter which is changed to uppercase.

The title of the message box must be specified by the TITLE option, while the MESSAGE option can be used to display an additional message. The special string @hrt in the MESSAGE option is translated into a hard return. Note that separate lines in the MESSAGE option are displayed without hard returns unless the special string @hrt is used. However a line with spaces only is displayed as an empty line. The WIDTH, FONT and SIZE options can be used to modify the display on screen.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

Restriction on the MESSAGE and DEFAULT options are ignored. The TEXT and VCHECK parameters are redefined in the procedure, and so restrictions on these parameters are ignored.

## References

None.

## Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

## Similar Procedures

QDIRECTORY returns a directory selected by means of a directory browse dialog box on screen. QFILENAME returns filename(s) selected by means of a file open box on screen. QMESSAGE displays a message on screen. QPICKLIST can be used to pick one or more items from a list presented on screen. QSTOPWATCH can be used to display timing information. QYESNO can be used to choose between alternatives Yes, No and Cancel on screen.

## Example

```
CAPTION 'QTEXT example' ; STYLE=meta
QTEXT [TITLE='Example 1 of QTEXT'] text
PRINT text
QTEXT [TITLE='Example 2 of QTEXT' ; MESSAGE='Input a string' ; \
DEFAULT=!t(Aap,Noot,Mies) ; NTIMES=3] text
PRINT text
```

## QTIMEDELAY

P.W. Goedhart

Pauses execution for a specific amount of time or until a file is not opened by another application

[contents](#) [previous](#) [next](#)

### Options

SECONDS = *scalar*                      Number of seconds to wait; default 5.

### Parameters

None

### Description

Procedure QTIMEDELAY can be used to pause execution of GenStat for a specific amount of time. This procedure uses an external C# program. The SECONDS option determines how many seconds are paused.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

### Similar Procedures

QMESSAGE can be used to display a message on screen for a specific number of seconds.

### Example

```
CAPTION 'QTIMEDELAY example' ; STYLE=meta
QTIMEDELAY [SECONDS=10]
```

## QYESNO

*P.W. Goedhart & L.C.P. Keizer*

Can be used to choose between alternatives Yes, No and Cancel on screen

[contents](#) [previous](#) [next](#)

### Options

TITLE = <i>text</i>	Single-valued text structure specifying the title of the screen box; must be set
MESSAGE = <i>text</i>	Text structure specifying a message to display; default *
BUTTONS = <i>string token</i>	Which buttons to display ( <i>yesno</i> , <i>okcancel</i> , <i>yesnocancel</i> ); default <i>yesnocancel</i>
ICON = <i>string token</i>	Displays an extra icon along with the message ( <i>none</i> , <i>question</i> , <i>error</i> , <i>warning</i> , <i>information</i> ); default <i>none</i>

### Parameters

CHOICE = <i>scalar</i>	Saves the selected button in a scalar with the value 1 (Yes), 0 (No) or -1 (Cancel); must be set
------------------------	--

### Description

Procedure QYESNO can be used to choose between Yes (or OK), No and Cancel buttons by means of a screen box. This procedure uses an external C# program. The buttons to display can be set by means of the BUTTONS option; default is to display all three buttons. The CHOICE parameter saves the selected button by means of a scalar with value 1 (Yes or OK), 0 (No) or -1 (Cancel).

The title of the message box must be specified by the TITLE option, while the MESSAGE option can be used to display an additional message. The special strings @hrt and @tab in the MESSAGE option are translated into hard returns and tabs respectively. Note that separate lines in the MESSAGE option are displayed without hard returns unless the special string @hrt is used. However a line with spaces only is displayed as an empty line in the message box. An extra icon can be displayed along the message by employing the ICON option.

### Method

The SUSPEND directive is used to invoke an external C# .NET Framework 3.5 program.

### Action with RESTRICT

Restrictions on the MESSAGE option are ignored.

### References

None.

### Procedures Used

The BIOMETRIS procedure is used to retrieve the filename of the external C# program.

### Similar Procedures

QDIRECTORY returns a directory selected by means of a directory browse dialog box on screen. QFILENAME returns a filename selected by means of a file open box on screen. QMESSAGE displays a message on screen. QPICKLIST can be used to pick one or more items from a list presented on screen. QSTOPWATCH can be used to display timing information. QTEXT can be used to obtain string(s) of a text structure from screen.

**Example**

```
CAPTION 'QYESNO example' ; STYLE=meta
TEXT    title ; 'Example of QYESNO'
TEXT    message ; VALUES=!t('Do you want to continue?', \
    '@hrtYes@tabresults in choice = 1', \
    '@hrtNo@tabresults in choice = 0' , \
    '@hrtCancel@tabresults in choice = -1')
QYESNO  [TITLE=title ; MESSAGE=message ; ICON=question] choice
PRINT   choice
```

## R2NEGBINOMIAL

R.M. Harbord, R.W. Payne &amp; P.W. Goedhart

Fits a negative binomial generalized linear model estimating the aggregation parameter

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	Printed output from the analysis (model, deviance, summary, estimates, correlations, fittedvalues, accumulated, monitoring, aggregation, loglikelihood); default mode, summ, esti, aggr
AGGREGATION = <i>scalar</i>	Saves the estimate of the aggregation parameter
_2LOGLIKELIHOOD = <i>scalar</i>	Saves the value of $-2 \times \log$ -likelihood
CONSTANT = <i>string token</i>	How to treat the constant (estimate, omit); default esti
FACTORIAL = <i>scalar</i>	Limit on number of factors in a treatment term; default 3
NOMESSAGE = <i>string tokens</i>	Warnings to suppress from FIT (dispersion, leverage, residual, aliasing, marginality, vertical, df, inflation, warnings); default *
FPROBABILITY = <i>string token</i>	Printing of probabilities for variance ratios (yes, no); default no
TPROBABILITY = <i>string token</i>	Printing of probabilities for t-statistics (yes, no); default no
SELECTION = <i>string tokens</i>	Statistics to be displayed in the summary of analysis produced by PRINT=summary (%variance, %ss, adjustedr2, r2, dispersion, %meandeviance, %deviance, aic, bic, sic); default disp
SEAGGREGATION = <i>scalar</i>	Saves the standard error of the estimated aggregation parameter
MAXCYCLE = <i>scalar or variate</i>	Maximum number of iteration for main, Newton-Raphson, FMINIMIZE and RCYCLE iterations; a single setting implies the same limit for all; default !(20, 20, 20, 50)
TOLERANCE = <i>scalar or variate</i>	Convergence criteria for deviance, aggregation, FMINIMIZE and RCYCLE; a single setting implies the same criterion for all; default !(1.0e-4, 1.0e-4, 1.0e-2, 1.0e-4)
LOWER = <i>scalar</i>	Lower limit of the aggregation parameter which is used for initial bracketing; default 0.01
UPPER = <i>scalar</i>	Upper limit of the aggregation parameter which is used for initial bracketing; default 1000
DF = <i>scalar</i>	Saves the residual degrees of freedom

### Parameters

TERMS = *formula* List of explanatory variates and factors, or model formula (as for FIT)

### Description

Procedure R2NEGBINOMIAL is a robust alternative to the RNEGBINOMIAL procedure. The latter procedure sometimes fails to estimate the aggregation parameter, further called index parameter or  $k$ , due to a naive starting value of the index parameter. R2NEGBINOMIAL employs the FMINIMIZE procedure to find a good starting value for  $k$  after which the usual Newton-Raphson method is used to solve the score equation for  $k$ . In addition to the options of RNEGBINOMIAL this procedure has options LOWER and UPPER which should bracket the estimate of the index parameter. Moreover the MAXCYCLE and TOLERANCE options have an extra element which is employed by the FMINIMIZE procedure. The remaining part of the description is largely copied from RNEGBINOMIAL.

The negative binomial distribution can be fitted as a generalized linear model using FIT only for a given value of the aggregation parameter  $k$ . R2NEGBINOMIAL extends the fitting to include estimation of  $k$  from the data. The negative binomial distribution is a discrete distribution with the relationship between mean and variance given by  $\text{variance} = \text{mean} + \text{mean} * \text{mean} / k$ , where  $k$  is a positive constant known as the aggregation parameter. It provides a possible model for count data that show apparent overdispersion when

a Poisson model is fitted. The call to R2NEGBINOMIAL must be preceded by a MODEL statement with option DISTRIBUTION=negativebinomial and LINK= logarithm.

The AGGREGATION option allows the estimate of  $k$  to be saved and SEAGGREGATION can be used to save the associated standard error. The \_2LOGLIKELIHOOD option allows saving of minus twice the maximized log-likelihood and DF can be used to save the residual degrees of freedom. This may be useful for comparing a sequence of nested models fitted by R2NEGBINOMIAL using likelihood ratio testing. Printed output is controlled by the PRINT option, which has the same settings as for the FIT directive but with the addition of aggregation to control the printing of the estimate of  $k$  and its standard error, and loglikelihood to print minus two times the log-likelihood.

The CONSTANT, FACTORIAL, NOMESSAGE, FPROBABILITY, TPROBABILITY, and SELECTION options operate in the usual way (as for example in the FIT directive). The NOMESSAGE options has an extra setting warnings which can be used to suppress warnings about non convergence of the iterative estimation procedure. The two options, MAXCYCLE and TOLERANCE, can supply variates of length 4 that are employed to control the iterative process if required. The first element of MAXCYCLE sets the maximum number of times that the model is fitted as a generalized linear model for fixed  $k$ , the second element sets the maximum number of Newton-Raphson iterations used to maximise the likelihood with respect to  $k$  for fixed fitted values, the third element sets the maximum number of iterations of the FMINIMIZE procedure which is used to obtain a good starting value for  $k$ , and finally the fourth element is used for setting the MAXCYCLE option of RCYCLE. The alternating cycle, controlled by the first two elements of MAXCYCLE, stops when successive values of the deviance are within a tolerance set by the first element of the TOLERANCE option and successive values of the deviance are within a tolerance set by the second element. The third element of TOLERANCE sets the convergence criterion of the FMINIMIZE procedure, while the fourth element sets the TOLERANCE option of RCYCLE.

## Method

For fixed  $k$ , the negative binomial distribution is in the exponential family and the regression parameters determining the fitted values can be fitted as a generalized linear model using the FIT directive. For a fixed set of fitted values,  $k$  can be estimated by using the Newton-Raphson method to solve the score equation for  $k$ . Alternating between the two processes until convergence yields joint maximum likelihood estimates of  $k$  and the regression parameters. As the estimate of  $k$  is asymptotically independent of the other regression parameters, their standard errors can be obtained separately from the two processes. The standard error for  $k$  uses observed rather than expected information due to the use of Newton-Raphson rather than Fisher scoring.

A good starting value of  $k$  is obtained by the FMINIMIZE procedure which finds a minimum in the bracketing interval as specified by the LOWER and UPPER options. Note that FMINIMIZE is operating on the logarithm of  $k$  rather than  $k$  itself.

## Action with RESTRICT

Any restriction applied to vectors used in the regression model applies also to the results from R2NEGBINOMIAL.

## References

None.

## Procedures Used

SUBSET, FMINIMIZE and %FMINIMIZE.

## Similar Procedures

RNEGBINOMIAL fits the negative binomial generalised linear model.

## RBETABINOMIAL

P.W. Goedhart

Fits the Beta-Binomial regression model to overdispersed proportions

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What to print (model, summary, estimates, correlations, monitoring); default model, summary, estimates
CONSTANT = <i>string token</i>	How to treat the constant (estimate, omit); default estimate
FACTORIAL = <i>scalar</i>	Limit for expansion of model terms; default 3
NOMESSAGE = <i>string tokens</i>	Which warning messages to suppress (aliasing, marginality, warning); default *
FULL = <i>string token</i>	Whether to assign all possible parameters to factors and interactions (yes, no); default no
RESIDUALS = <i>variate</i>	Saves the Pearson residuals
FITTEDVALUES = <i>variate</i>	Saves the fitted values
ESTIMATES = <i>variate</i>	Saves the estimates of the regression parameters
SE = <i>variate</i>	Saves the standard errors of the estimates of the regression parameters
VCOVARIANCE = <i>symmetric matrix</i>	Saves the variance-covariance matrix of the regression estimates
PHI = <i>scalar</i>	Saves the estimated overdispersion parameter $\phi$
SEPHI = <i>scalar</i>	Saves the standard error of the estimated overdispersion parameter $\phi$
FULLVCOVARIANCE = <i>symmetric matrix</i>	Saves the full variance-covariance matrix of all parameters, corrected for estimation of the overdispersion parameter $\phi$
_2LOGLIKELIHOOD = <i>scalar</i>	Saves the value of $-2 \times \log$ -likelihood
DF = <i>scalar</i>	Saves the residual degrees of freedom
SAVE = <i>pointer</i>	Saves additional structures
METHOD = <i>string token</i>	Algorithm for fitting the overdispersion parameter $\phi$ (Brent, mBrent, NewtonRaphson, N2ewtonRaphson, GoldenSectionSearch); default NewtonRaphson
MAXCYCLE = <i>scalar</i>	Maximum number of iterations; default 30
TOLERANCE = <i>scalar</i>	Convergence criterion; default 0.0001
INITIAL = <i>scalar or variate</i>	Initial values for the overdispersion parameter $\phi$ to start the iterative process; default !(0.0001, 0.01, 0.05, 0.1, 0.3, 0.5, 0.75, 0.9999)
FIXPHI = <i>string token</i>	Whether to fix the overdispersion parameter $\phi$ to the value provided by the PHI option (yes, no); default no

### Parameters

TERMS = *formula* List of explanatory variates and factors, or model formula

### Description

In binomial regression models, residual variability is often larger than would be expected if the data were indeed binomially distributed. This may be due to a few outliers or a poor choice of link function but often it simply indicates that the data are from a distribution more variable than the binomial. Such data are said to be "overdispersed" or to exhibit "extra-binomial variation". One way of dealing with binomial overdispersion is to assume that the data follow the Beta-Binomial distribution, see Crowder (1978) for an early reference. The Beta-Binomial distribution arises by assuming that the probability  $p$  of success follows a Beta( $\alpha$ ,  $\beta$ ) distribution and that conditionally on  $p$  the data are binomially( $n$ ,  $p$ ) distributed. The mean and variance of the Beta-Binomial are given by  $n\pi$  and  $n\pi(1-\pi)(1 + \phi(n-1))$  respectively with  $\pi = \alpha/(\alpha+\beta)$  and overdispersion parameter  $\phi = 1/(1+\alpha+\beta)$ . The overdispersion parameter  $\phi$  is limited to the interval (0,1). The response probability  $\pi$  is then related to the model formula employing one of the standard binomial link functions. Maximum likelihood is used to estimate the regression parameters and the overdispersion parameter  $\phi$ . Note that Williams (1982) model II, implemented by the EXTRABINOMIAL procedure, is

similar in spirit but uses only the first two moments of the Beta-Binomial distribution to estimate the parameters.

A call to the RBETABINOMIAL procedure must be preceded by a MODEL statement with option setting DISTRIBUTION=binomial and LINK option set to either logit, probit or complementaryloglog. The user can also choose to set the WEIGHTS, OFFSET and GROUPS options of the MODEL directive.

The options and parameter of RBETABINOMIAL are similar in many ways to the standard regression directives. There is a single parameter TERMS to define the model terms to be fitted, and the first four options, PRINT, CONSTANT, FACTORIAL, and NOMESSAGE, all have the same syntax and purpose as in FIT. The FULL option has the same purpose as in TERMS. The warning setting of NOMESSAGE suppresses warnings messages concerning the iterative fitting algorithm.

The model is fitted by an iterative process as specified by the METHOD option using either a form of Newton-Raphson (the default) or Golden Section Search. The MAXCYCLE option specifies the number of iterations, and the TOLERANCE option defines the convergence criterion. Initial values for the overdispersion parameter  $\phi$  can be specified by means of the INITIAL option. Full details of the iterative procedure and the way in which the initial values are handled are given in the Method section. The iterative process can be monitored by specifying PRINT=monitoring; this will first display monitoring of the way in which an initial value for  $\phi$  is obtained, followed by monitoring of the iterative process itself. Alternatively, setting FIXPHI=yes will fit the model for a fixed value of the overdispersion parameter  $\phi$ ; the fixed value must then be specified by means of the PHI option.

A large number of options can be used to save results from the fitted model, most of which are similar to the RKEEP directive. Fitted values and Pearson residuals can be saved by means of the FITTEDVALUES and RESIDUALS options. The ESTIMATES, SE and VCOVARIANCE options save results for the regression parameters, while PHI and SEPHI save the estimate of the overdispersion parameter  $\phi$  and its standard error. Note that all standard errors and variances thus saved are corrected for the estimation of  $\phi$ . The full covariance matrix with covariances between the regression parameters and the dispersion parameter can be saved by means of the FULLVCOVARIANCE option. The value of minus twice the maximized log-likelihood and the corresponding degrees of freedom can be saved by means of the \_2LOGLIKELIHOOD and DF options. This may be useful to compare nested model employing a likelihood ratio test.

Additional results can be saved by setting the SAVE option. This will save, in a pointer, (1) logit( $\phi$ ); (2) the standard error of logit( $\phi$ ); (3) the linear predictor; (4) the leverage; (5) the iterative weights; (6) the adjusted response; (7) the standard errors of the linear predictor; (8) the score with the first order derivative of the log-likelihood with respect to the linear predictor; (9) the contribution of each unit to the value of minus twice the maximized log-likelihood; (10) the value of the  $\alpha$  parameter for each unit; (11) the value of the  $\beta$  parameter for each unit; (12) the variance of the Beta-Binomial distribution for each unit; (13) the conditional expectation of the probability given the observed value which is termed blup; (14) the number of cycles of the iterative procedure; (15) a logical value indicating non-convergence; three logical values indicating that the estimate of phi is (16) close to a limit as specified by INITIAL, (17) equal to the lower bound 0.0001, (18) equal to the upper bound 0.9999.

## Method

For a fixed overdispersion parameter  $\phi$ , all parameters are linear and iteratively reweighted least squares using expected information can be used to maximize the log-likelihood (Stirling, 1984). The log-likelihood only employs the LNGAMMA functions and so the first and second order derivatives are calculate by means of the DIGAMMA and TRIGAMMA function.

The overdispersion parameter  $\phi$  can be estimated by the Newton-Raphson method to solve the score equation for  $\phi$  (for a fixed set of fitted values). The overdispersion parameter  $\phi$  is, by definition, in the interval (0,1). Therefore the score equation for logit( $\phi$ ), rather than  $\phi$  itself, is used. Alternating between the two processes, i.e. fixing  $\phi$  and fixing the fitted values, until convergence yields joint maximum likelihood estimates of  $\phi$  and the regression parameters. The iteration stops when the maximum relative change in fitted values in successive iterations is less than the tolerance, or in case the iteration number exceeds 10, when the relative change in the value of minus twice the log-likelihood is less than the tolerance divided by 1000. This all is used by the METHOD settings NewtonRaphson and N2ewtonRaphson. These two methods only differ in the way an initial value for  $\phi$  is derived. The first method employs a modified

version of the EXTRABINOMIAL procedure with starting value equal to the first element of INITIAL. The second method first fits the model for a number of fixed values of  $\phi$  as set by the INITIAL option. This method also uses the fact that the log-likelihood as a function of  $\phi$  is convex.

Alternatively the overdispersion parameter  $\phi$  is estimated by a form of Golden Section Search as implemented in procedure FMINIMIZE. An initial bracketing interval is obtained by subsequently fitting the model for a number of fixed values of  $\phi$  as set by the INITIAL option. See FMINIMIZE for the convergence criterion.

For most datasets METHOD=NewtonRaphson will give maximum likelihood estimates in a limited number of iterations. Occasionally, e.g. due to a flat likelihood, this estimation method fails and then METHOD=brent provides a robust alternative.

The estimate of  $\phi$  is not asymptotically independent of the regression parameters, and so a corrected variance-covariance matrix is calculated by means of the method outlined in Stirling (1984). The variance-covariance matrices, and standard errors, use observed rather than expected information as there is no closed form available for expected information. A confidence interval for  $\phi$  can be calculated best on the logit scale, and therefore  $\text{logit}(\phi)$  and its estimated standard error can be saved by means of the SAVE option.

### Action with RESTRICT

Only the response variate can be restricted and the analysis is restricted accordingly.

Fits a censored regression model with normal errors

[contents](#) [previous](#) [next](#)**Options**

PRINT = <i>string tokens</i>	What to print (model, summary, estimates, correlations, monitoring); default model, summary, estimates
CONSTANT = <i>string token</i>	How to treat the constant (estimate, omit); default estimate
FACTORIAL = <i>scalar</i>	Limit for expansion of model terms; default 3
NOMESSAGE = <i>string tokens</i>	Which warning messages to suppress (aliasing, marginality, warning); default *
FULL = <i>string token</i>	Whether to assign all possible parameters to factors and interactions (yes, no); default no
LOWER = <i>scalar or variate</i>	Lower censoring limit; default *, i.e. no left censoring
UPPER = <i>scalar or variate</i>	Upper censoring limit; default *, i.e. no right censoring
RESIDUALS = <i>variate</i>	Saves the simple residuals
FITTEDVALUES = <i>variate</i>	Saves the fitted values
ESTIMATES = <i>variate</i>	Saves the estimates of the regression parameters
SE = <i>variate</i>	Saves the standard errors of the estimates of the regression parameters
VCOVARIANCE = <i>symmetric matrix</i>	Saves the variance-covariance matrix of the regression estimates
SIGMA2 = <i>scalar</i>	Saves the estimate of the residual variance
SESIGMA2 = <i>scalar</i>	Saves the standard error of the estimated residual variance
FULLVCOVARIANCE = <i>symmetric matrix</i>	Saves the full variance-covariance matrix of the regression parameters and the residual variance
_2LOGLIKELIHOOD = <i>scalar</i>	Saves the value of $-2 \times \log$ -likelihood
DF = <i>scalar</i>	Saves the residual degrees of freedom
SAVE = <i>pointer</i>	Saves additional structures
MAXCYCLE = <i>scalar</i>	Maximum number of iterations; default 30
TOLERANCE = <i>scalar</i>	Convergence criterion; default 1.0e-6
INITIAL = <i>scalar or variate</i>	Initial fitted values to start the iterative process; default *

**Parameters**

TERMS = <i>formula</i>	List of explanatory variates and factors, or model formula
------------------------	--

**Description**

An observation is said to be censored if it is known only that it is less than (or greater than) a particular value. Censoring is thus a data problem: whenever an observation is outside the interval [L, U], the value of the observation is recorded as L or U rather than the true value. Left-censoring, for example, occurs frequently in analytical chemistry where a chemical may be present in a sample but is "non-detectable" due to the analytical method used. In that case the so called Limit Of Detection is reported. An example of right-censoring is the lifetime of electric light-bulbs: it may happen that some bulbs are still alight when the experiment has to be concluded. In econometrics censored regression is usually called the tobit model. Censoring should not be confused with truncation. Truncation occurs when it is impossible to observe a value outside a certain interval, i.e. the number of employees in a survey which excludes firms with less than 10 employees.

A call to the RCENSORED procedure must be preceded by a MODEL statement with default option settings DISTRIBUTION=normal and LINK=identity. The user can also choose to set the WEIGHTS, OFFSET and GROUPS options of the MODEL directive. The censoring limits are set by means of the LOWER and UPPER options. These can be either set to scalars implying an equal censoring limit across observations, or to variates when the censoring values are different. The other options and the single parameter of RCENSORED are similar to the standard regression directives. The single parameter TERMS

defines the model terms to be fitted, and the first four options, PRINT, CONSTANT, FACTORIAL, and NOMESSAGE, all have the same syntax and purpose as in FIT. The FULL option has the same purpose as in TERMS. The model is fitted by maximum likelihood using iteratively re-weighted least squares. The MAXCYCLE option specifies the number of iterations, and the TOLERANCE option defines the convergence criterion. Initial values for fitted values can be set by means of the INITIAL option.

A large number of options can be used to save results from the fitted model, most of which are similar to the RKEEP directive. Fitted values and simple residuals can be saved by means of the FITTEDVALUES and RESIDUALS options. The ESTIMATES, SE and VCOVARIANCE options save results for the regression parameters, while SIGMA2 and SESIGMA2 save the estimate of the residual variance and its standard error. The FULLVCOVARIANCE option can be employed to save the variance-covariance matrix of the regression parameters. Note that all standard errors and (co)variances are adjusted for the estimation of the residual variance. The value of minus twice the maximized log-likelihood and the corresponding degrees of freedom can be saved by means of the \_2LOGLIKELIHOOD and DF options. This may be useful to compare nested models employing a likelihood ratio test.

Additional results can be saved by setting the SAVE option. This will save, in a pointer, (1) the leverage; (2) the iterative weights; (3) the adjusted response; (4) the score with the first order derivative of the log-likelihood with respect to the linear predictor; (5) the contribution of each unit to the value of minus twice the maximized log-likelihood; (6) the estimate of  $\text{Log}(\text{Sqrt}(\text{residual variance}))$ ; (7) the corresponding standard error; (8) the full variance-covariance matrix with parameter  $\text{Log}(\text{Sqrt}(\text{residual variance}))$ ; (9) the number of cycles of the iterative procedure; (10) a logical value indicating non-convergence.

## Method

For a fixed value of the residual variance, all parameters are linear and iteratively reweighted least squares using observed information can be used to maximize the log-likelihood (Stirling, 1984). The residual variance can be estimated by the Newton-Raphson method to solve its score equation (for a fixed set of fitted values). The residual variance is, by definition, positive and therefore the score equation of  $\text{log}(\text{sqrt}(\text{residual variance}))$  is used. Alternating between the two processes, i.e. fixing the residual variance and fixing the fitted values, until convergence yields joint maximum likelihood estimates of the residual variance and the regression parameters. The iteration stops when the relative change in the value of minus twice the log-likelihood is less than the tolerance. The estimate of the residual variance is not asymptotically independent of the regression parameters, and so a corrected variance-covariance matrix is calculated by means of the method outlined in Stirling (1984) using observed information.

## Action with RESTRICT

Only the response variate can be restricted and the analysis is restricted accordingly. Fitted values and residuals are set to missing for units excluded by the restriction.

## RENAMEPOINTER

L.C.P. Keizer, J.T.N.M. Thissen &amp; P.W. Goedhart

Renames the structures of a pointer

[contents](#) [previous](#) [next](#)

### Options

REDEFINE = *string token*

Whether to allow an identifier which is already defined in the program to be redefined when it appears in the NAME text (yes, no); default no

SCOPE = *string tokens*

Which scope to use when REDEFINE=no; the strings in NAME are compared with already existing identifiers in the calling program or procedure (SCOPE=external) or against identifiers in the main outermost program (SCOPE=global); default external, global

### Parameters

POINTER = *pointers*

Pointer whose structures are to be renamed; must be set

NAME = *texts*

Text structure with new names for the structures of POINTER; must be set

### Description

Procedure RENAMEPOINTER can be used to rename the structures of a pointer. The pointer and new names must be specified by means of the POINTER and NAME parameters. The length of NAME should be equal to the number of structures of POINTER.

Setting REDEFINE=yes allows identifiers which are already defined in the program to be redefined by RENAMEPOINTER. An example in which this is necessary is given by

```
VARIATE variate, response ; VALUES=(1...3), !(1...10)
POINTER [VALUES=variate] pointer
RENAMEPOINTER pointer ; !t(response)
```

In case REDEFINE=no, the SCOPE option defines which scope to use for checking that identifiers are already defined. Note that when RENAMEPOINTER is called from the main program there is no difference between the external and global settings.

### Method

The SETNAME procedure is used in a loop. This implies that the scope of the renamed identifiers is always global.

### Action with RESTRICT

Restrictions on the NAME parameter are ignored.

### References

None.

### Procedures Used

None.

### Similar Procedures

SETNAME sets the identifier of a data structure to be one specified in a text. FPOINTER forms a pointer from a text structure.

**Example**

```

RENAMEPOINTER POINTER=x ; NAME=newname
PRINT       x[] ; FIELD=12
```

## RGDISPLAY

P.W. Goedhart

Displays and stores the non-groups parameters of a within-groups regression

[contents](#) [previous](#) [next](#)

### Options

PRINT = *string token*Printed output required (*estimates*); default *estimates*

### Parameters

ESTIMATES = *variate*

To save estimates of the non-groups parameters of a within-groups regression

SE = *variate*

To save standard errors of the estimates of the non-groups parameters

VCOVARIANCE = *symmetric matrix*

To save the variance-covariance matrix of the estimates of the non-groups parameters

LABELS = *text*

To save labels of the estimates of the non-groups parameters

EGROUPS = *variate*

To save estimates of the groups parameters

SEGROUPS = *variate*

To save standard errors of the estimates of the groups parameters

### Description

A within-groups regression model can be fitted by specifying the GROUPS option in the MODEL directive. Use of GROUPS gives less information than you would get if you included the grouping factor explicitly in the model, because leverages, predictions and some parameter correlations are not formed, but it saves space and time in fitting the model when the groups factor has many levels. After such a model is fitted, all the estimated groups parameters are standardly displayed and stored. However, these parameters are frequently of less interest. Procedure RGDISPLAY can be used to display and store the non-groups parameters only. The estimates, standard errors, variance-covariance matrix and labels can be saved by means of parameters ESTIMATES, SE, VCOVARIANCE and LABELS. The estimates of the groups parameters and their standard errors can be saved by means of EGROUPS and SEGROUPS. The PRINT option can be used to suppress printing of the estimates.

### Method

The information about the GROUPS option of the MODEL directive is retrieved by means of the OMODEL option of RKEEP. The LABELS are retrieved from the special regression save structure.

### Action with RESTRICT

Not relevant.

### Procedures Used

None.

### Similar Procedures

None.

## RLMS

P.W. Goedhart

Does regression by least median squares

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	Printed output required (model, estimates, fittedvalues); default model, estimates
CONSTANT = <i>string token</i>	How to treat constant (estimate, omit); default estimate
INDEXPLOT = <i>string tokens</i>	What to display in an indexplot (residuals, diagnostics); default *
ALGORITHM = <i>string token</i>	Which algorithm to use (extensive, quick); default extensive
NOMESSAGE = <i>string token</i>	Which warning messages to suppress (residuals, warnings); default *

### Parameters

X = <i>pointers</i>	Pointer containing the predictor variables to enter the LMS regression
RESIDUALS = <i>variates</i>	To save the residuals of the LMS regression
FITTEDVALUES = <i>variates</i>	To save the fitted values of the LMS regression
DIAGNOSTICS = <i>variates</i>	To save the resistant diagnostics of the LMS regression
ESTIMATES = <i>variates</i>	To save the estimated parameters of the LMS regression
SCALE = <i>scalars</i>	To save the scale estimate of the LMS regression

### Description

This procedure uses an external C# program. Classical least squares regression (LS) consists of minimizing the sum of squared residuals. Outliers, both in the response variable and in the predictor variables, may have a strong influence on the least squares estimates. Outliers can be identified by diagnostic techniques using residuals and leverages. However, even careful residual analysis may not always reveal (multiple) outliers. Moreover, the successful use of diagnostic procedures often requires abilities beyond those of a naive user of regression techniques.

To remedy these problems, robust regression methods have been developed that are not so easily affected by outliers. Observations far away from the robust fit are then identified by their large residuals from it. One such technique is least median squares (LMS) in which the *median* of the squared residuals is minimized, see Rousseeuw (1984) or Rousseeuw and Leroy (1987). In the special case of simple linear regression, LMS corresponds to finding the narrowest strip covering half of the observations.

A call to RLMS must be preceded by a MODEL statement in which the response variable is specified. Only the first response variable is analysed and the WEIGHTS, OFFSET and GROUPS options of MODEL are ignored for the LMS fit. Generalized linear models are not allowed. Parameter X specifies the set of predictors to enter the regression. The CONSTANT option controls whether the constant parameter should be included in the model. Residuals, fitted values and estimates of the least median squares regression can be saved using parameters RESIDUALS, FITTEDVALUES and ESTIMATES. DIAGNOSTICS saves the resistant diagnostic which aims at identifying all points that are either outliers or large leverage points. A resistant diagnostic exceeding 2.5 is considered to be large. SCALE saves a robust estimate of scale which is essentially the residual standard deviation of the units with small residuals. The resistant diagnostic and the scale estimate are fully defined in Rousseeuw and Leroy (1987, page 238 and 202). RKEEP can be used to store results of the ordinary least squares regression which is also performed in the procedure.

Output is controlled by the PRINT and INDEXPLOT options. The model and estimates settings of PRINT are default and give a description of the model and estimates of both the LMS and the ordinary LS regression along with estimates of scale. If the LS fit agrees closely with the LMS fit, the LS result can be trusted. The fittedvalues setting of PRINT gives a table of unit labels, response variate, fitted values, residuals (scaled by the estimate of scale) and resistant diagnostics. Option INDEXPLOT provides indexplots of residuals and diagnostics, which are displayed in the first graphical window using the first pen. The NOMESSAGE=residuals setting hides printing of warning messages of units with a residual

larger than 2.0 or a diagnostic larger than 2.5. The `warnings` setting hides printing of a message when random subsamples lead to a singular system of equations. No residual warnings are printed when `PRINT` is set to `fittedvalues`.

Computation of LMS is similar in spirit to the bootstrap. The `ALGORITHM` option controls the number of subsamples to be drawn for a given data set. In general the setting `extensive` is advised.

## Method

The procedure passes the problem to a C# .NET Framework 3.5 program by using the `SUSPEND` directive. The C# program is a translation of the Fortran program `PROGRESS` (Leroy and Rousseeuw, 1984). The algorithm is similar in spirit to the bootstrap. With  $p$  explanatory variables, it repeatedly draws subsamples of  $p$  different observations, determines the exact fitting regression surface through the  $p$  points and calculates the median of the squared residuals with respect to the whole data set. The subsample with minimal median is retained. This implies that different LMS estimates can be obtained by changing the order of the observations. The number of subsamples depends on the number of observations, the number of regressors and the setting of option `ALGORITHM` (Rousseeuw and Leroy, 1987).

## Action with RESTRICT

Only the response variate can be restricted an the analysis is restricted accordingly. Parameters `RESIDUALS`, `FITTEDVALUES` and `DIAGNOSTICS` are not restricted on output.

VCOVARIANCE = <i>symmetric matrix</i>	Saves the variance-covariance matrix of the regression estimates
PHI = <i>scalar</i>	Saves the estimated overdispersion parameter $\phi$
SEPHI = <i>scalar</i>	Saves the standard error of the estimated overdispersion parameter $\phi$
FULLVCOVARIANCE = <i>symmetric matrix</i>	Saves the full variance-covariance matrix of all parameters, i.e. the regression parameters and the dispersion parameter
_2LOGLIKELIHOOD = <i>scalar</i>	Saves the value of $-2 \times \log$ -likelihood
DF = <i>scalar</i>	Saves the residual degrees of freedom
SAVE = <i>pointer</i>	Saves additional structures
METHOD = <i>string token</i>	Algorithm for fitting the overdispersion parameter $\phi$ (Brent, mBrent, GoldenSectionSearch, NewtonRaphson, N2ewtonRaphson); default Brent
NPOINTS = <i>scalar</i>	Number of integration points for Gauss-Hermite integration; default 32
ADAPTIVE = <i>string token</i>	Whether to apply adaptive Gauss-Hermite integration (yes, no); default yes
MAXCYCLE = <i>scalar</i>	Maximum number of iterations; default 30
TOLERANCE = <i>scalar</i>	Convergence criterion; default 0.0001
INITIAL = <i>scalar or variate</i>	Initial values for the overdispersion parameter $\phi$ to start the iterative process; default !(0.0001, 0.01, 0.1, 1, 10, 100, 1000)
FIXPHI = <i>string token</i>	Whether to fix the overdispersion parameter $\phi$ to the value provided by the PHI option (yes, no); default no

## Parameters

TERMS = *formula* List of explanatory variates and factors, or model formula

## Description

In binomial regression models, residual variability is often larger than would be expected if the data were indeed binomially distributed. This may be due to a few outliers or a poor choice of link function but often it simply indicates that the data are from a distribution more variable than the binomial. Such data are said to be "overdispersed" or to exhibit "extra-binomial variation". One way of dealing with binomial overdispersion is to assume that there is an extra normally distributed random effect, with mean zero and variance  $\phi$ , on the scale of the linear predictor. The resulting distribution is sometimes termed Logit-Normal. The RLOGITNORMAL procedure estimates the parameters of this model using Maximum Likelihood. The likelihood cannot be calculated analytically and therefore (adaptive) Gauss-Hermite integration is used. This is an approximate method which is sometimes inaccurate without giving notice,

see Lesaffre & Spiessens (2001). Numerical precision is generally increased by using adaptive Gauss-Hermite integration, see Liu & Pierce (1994). Note that Williams (1982) model III, implemented by the EXTRABINOMIAL procedure, fits the same model using only the first two moments of the Logit-Normal distribution to estimate the parameters.

A call to the RLOGITNORMAL procedure must be preceded by a MODEL statement with option setting DISTRIBUTION=binomial and LINK option set to either logit, probit or complementaryloglog. The user can also choose to set the WEIGHTS, OFFSET and GROUPS options of the MODEL directive.

The options and parameter of RLOGITNORMAL are similar in many ways to the standard regression directives. There is a single parameter TERMS to define the model terms to be fitted, and the first four options, PRINT, CONSTANT, FACTORIAL, and NOMESSAGE, all have the same syntax and purpose as in FIT. The FULL option has the same purpose as in TERMS. The warning setting of NOMESSAGE suppresses warnings messages concerning the iterative fitting algorithm.

The number of Gauss-Hermite integration points can be specified by the NPOINTS option. It is advised to use sufficient integration points especially when the dispersion parameter is large. Setting ADAPTIVE to the default value yes will generally increase numerical precision. The model is fitted by an iterative process as specified by the METHOD option using either a form of Newton-Raphson or a form of Golden Section Search. The MAXCYCLE option specifies the number of iterations, and the TOLERANCE option defines the convergence criterion. Initial values for the overdispersion parameter  $\phi$  can be specified by means of the INITIAL option. Full details of the iterative procedure and the way in which the initial values are handled are given in the Method section. The iterative process can be monitored by specifying PRINT=monitoring; this will first display monitoring of the way in which an initial value for  $\phi$  is obtained, followed by monitoring of the iterative process itself. Alternatively, setting FIXPHI=yes will fit the model for a fixed value of the overdispersion parameter  $\phi$ ; the fixed value must then be specified by means of the PHI option.

A large number of options can be used to save results from the fitted model, most of which are similar to the RKEEP directive. Fitted values and leverage corrected Pearson residuals can be saved by means of the FITTEDVALUES and RESIDUALS options. The ESTIMATES, SE and VCOVARIANCE options save results for the regression parameters, while PHI and SEPHI save the estimate of the overdispersion parameter  $\phi$  and its standard error. Note that all standard errors and variances thus saved are corrected for the estimation of  $\phi$ . The full covariance matrix with covariances between the regression parameters and the dispersion parameter can be saved by means of the FULLVCOVARIANCE option. The value of minus twice the maximized log-likelihood and the corresponding degrees of freedom can be saved by means of the \_2LOGLIKELIHOOD and DF options. This may be useful to compare nested model employing a likelihood ratio test.

Additional results can be saved by setting the SAVE option. This will save, in a pointer, (1)  $\log(\phi)$ ; (2) the standard error of  $\log(\phi)$ ; (3) the linear predictor; (4) the leverage; (5) the iterative weights which includes the regression weights; (6) the adjusted response; (7) the standard errors of the linear predictor; (8) the score with the first order derivative of the log-likelihood with respect to the linear predictor; (9) the contribution of each unit to the value of minus twice the maximized log-likelihood; (10) the variance of the Logit-Normal distribution for every value of the linear predictor; (11) the conditional expectation of the probability given the observed value which is termed blup; (12) the number of cycles of the iterative procedure; (13) a logical value indicating non-convergence; three logical values indicating that the estimate of  $\phi$  is (14) close to a limit as specified by INITIAL, (15) equal to the lower bound 0.0001, (16) equal to the upper bound 1000.

## Method

For a fixed overdispersion parameter  $\phi$ , all parameters are linear and iteratively reweighted least squares (IRLS) can be used to maximize the log-likelihood (Stirling, 1984). The log-likelihood is intractable and (adaptive) Gauss-Hermite integration is used to approximate it.

The overdispersion parameter  $\phi$  can be estimated by the Newton-Raphson method to solve the score equation for  $\phi$  (for a fixed set of fitted values). The overdispersion parameter  $\phi$  is, by definition, positive and therefore the score equation for  $\log(\phi)$ , rather than  $\phi$  itself, is used. Alternating between the two processes, i.e. IRLS and Newton-Raphson, until convergence yields joint maximum likelihood estimates of

$\phi$  and the regression parameters. The iteration stops when the maximum relative change in likelihood contributions in successive iterations is less than the tolerance, or in case the iteration number exceeds 10, when the relative change in the value of minus twice the log-likelihood is less than the tolerance divided by 1000. This all is used by the METHOD settings `NewtonRaphson` and `N2ewtonRaphson`. These two methods only differ in the way an initial value for  $\phi$  is derived. The first method employs a modified version of the `EXTRABINOMIAL` procedure with starting value equal to the first element of `INITIAL`. The second method first fits the model for a number of fixed values of  $\phi$  as set by the `INITIAL` option, and then interpolates to an initial value of  $\phi$  with minimal log-likelihood. This last method also uses the fact that the log-likelihood as a function of  $\phi$  is convex.

Alternatively the overdispersion parameter  $\phi$  is estimated by a form of Golden Section Search as implemented by the `FMINIMIZE` procedure. An initial bracketing interval is obtained by subsequently fitting the model for a number of fixed values of  $\phi$  as set by the `INITIAL` option. See `FMINIMIZE` for the convergence criterion.

For most datasets `METHOD=NewtonRaphson` will give maximum likelihood estimates in a limited number of iterations. Occasionally, e.g. due to a flat likelihood, this estimation method fails and then `METHOD=brent` provides a robust alternative.

The estimate of  $\phi$  is not asymptotically independent of the regression parameters, and so a corrected variance-covariance matrix is calculated by means of the method outlined in Stirling (1984). The variance-covariance matrices, and standard errors, use observed rather than expected information as there is no closed form available for expected information. A confidence interval for  $\phi$  can be calculated best on the log scale, and therefore  $\log(\phi)$  and its estimated standard error can be saved by means of the `SAVE` option. Note that the standard errors of the linear predictor are saved from the last IRLS fit and are thus **not** corrected for the estimation of  $\phi$ .

### Action with **RESTRICT**

Only the response variate can be restricted and the analysis is restricted accordingly.

# RMLSTACK

P.W. Goedhart

Stacks data to allow the fitting of a multinomial logistic regression model

[contents](#) [previous](#) [next](#)

## Options

OLDRESPONSE = <i>factor</i> or <i>variates</i>	Specifies the multinomial response, either as a list of variates or as a single factor for presence/absence data; must be set.
NEWRESPONSE = <i>variate</i>	Saves the multinomial response as a stacked variate; must be set
GROUPS = <i>factor</i>	Saves a stacked factor which corresponds to the original units; must be set
CATEGORY = <i>factor</i>	Saves a stacked factor which corresponds to the multinomial categories; must be set
IDUNITS = <i>variate</i> or <i>text</i>	Specifies the labels of the GROUPS factor

## Parameters

OLDVECTORS = <i>variates</i> and/or <i>factors</i>	List of explanatory variates and/or factors which will be used in the multinomial logistic regression model
NEWVECTORS = <i>variates</i> and/or <i>factors</i>	Saves the stacked explanatory variates and/or factors

## Description

The multinomial logistic regression model, see e.g. section 5.2.4 of McCullagh and Nelder (1989), can be fitted by employing a relation between the multinomial and Poisson likelihood. Suppose the multinomial responses are available as a set of variates, one variate for each category. Suppose further that there are a number of explanatory variates and/or factors. To fit the multinomial logistic regression model in the GLM Poisson framework, the set of response variates must first be stacked into a single variate. The explanatory vectors must also be stacked by repeating their values. Moreover a factor is needed which corresponds to the multinomial categories of the stacked response, as well as a groups factor defining the original units. The parameters of the multinomial logistic model can then be obtained by fitting interactions between the category factor and the explanatory vectors. The fitted model must contain in addition a parameter for each original unit, which can be handled by employing the GROUPS option of the MODEL directive.

The multinomial response must be specified by means of the OLDRESPONSE option. If OLDRESPONSE is set to a list of variates, NEWRESPONSE saves the stacked variates. Alternatively when OLDRESPONSE is set to a single factor, a set of variates is created internally, one for each factor level. Each variate contains presence (1) or absence (0) of the corresponding factor level, and NEWRESPONSE saves the stacked variates. The groups factor and multinomial categories factor must be saved by means of the options GROUPS and CATEGORY. The IDUNITS option can be set to specify the labels of the GROUPS factor. Labels of the CATEGORY factor are set to the names of the OLDRESPONSE variates or are duplicated from the OLDRESPONSE factor. The original explanatory vectors, which must all be of the same length as the OLDRESPONSE parameter, are specified by the OLDVECTORS parameter and identifiers for the vectors to contain the stacked vectors are specified by the NEWVECTORS parameter. If NEWVECTORS is not set, the OLDVECTORS vectors are redefined to store the stacked vectors instead of their original values. The multinomial logistic regression model can then be fitted as follows

```
RMLSTACK [OLDRESPONSE=y[1...3] ; NEWRESPONSE=ystack ; \
          GROUPS=group ; CATEGORY=cat] variate, factor ; vstack, fstack
MODEL   [DISTRIBUTION=poisson ; GROUPS=group] ystack
FIT     [NOMESSAGE=alias] cat/(fstack*vstack)
```

## Method

The procedure uses standard GenStat directives for data manipulation.

## Action with RESTRICT

The OLDRESPONSE variates or factor can be restricted. The number of values of the NEWRESPONSE variate is as if the OLDRESPONSE structures have not been restricted, but the NEWRESPONSE variate has missing values for units excluded by the restriction. Restrictions on the OLDVECTORS vectors are ignored.

# RMLUNSTACK

P.W. Goedhart

Unstacks results of a multinomial logistic regression model

[contents](#) [previous](#) [next](#)

## Options

GROUPS = <i>factor</i>	Specifies the stacked groups factor which corresponds to the original units of the multinomial response; must be set
CATEGORY = <i>factor</i>	Specifies the stacked factor which corresponds to the multinomial categories; must be set
CONDITION = <i>expression</i>	Logical expression to define which units are to be included

## Parameters

RESULTS = <i>variates</i>	Specifies results (fittedvalues, residuals, leverages) of a multinomial logistic regression model
SRESULTS = <i>pointers</i>	Saves results for each multinomial category
SPROBABILITIES = <i>pointers</i>	Saves fitted probabilities for each multinomial category; only useful when RESULTS is set to fittedvalues

## Description

Procedure RMLSTACK can be used to prepare multinomial data for the fitting of a multinomial logistic regression model. RMLUNSTACK can be used to convert the stacked results, such as fittedvalues or residuals, of such a model to a pointer of variates, one variate with results for each multinomial category. In addition, for fittedvalues, a pointer of fitted probabilities can be saved.

The GROUPS and CATEGORY options settings must be identical to those used in the RMLSTACK procedure. The results of the multinomial logistic regression model must be specified by the RESULTS parameter, and pointers to “unstacked” results and probabilities can be saved by means of SRESULTS and SPROBABILITIES. The CONDITION option can be used to save a limited number of units. The CONDITION expression must yield a variate with number of values equal to the number of levels of the GROUPS factor.

## Method

The procedure uses standard GenStat directives for data manipulation. The fitted probabilities in the pointer SPROBABILITIES are obtained by dividing SRESULTS[ ] by the sum of SRESULTS[ ].

## Action with RESTRICT

The GROUPS and CATEGORY options must not be restricted. Restrictions on the RESULTS parameter are ignored.

## References

None.

## Procedures Used

## Description

In Poisson regression models, residual variability is often larger than would be expected if the data indeed follow a Poisson distribution. This may be due to a few outliers or a poor choice of link function but often it simply indicates that the data are from a distribution more variable than the Poisson. Such data are said to be "overdispersed" or to exhibit "extra-Poisson variation". One way of dealing with Poisson overdispersion is to assume that there is an extra normally distributed random effect, with mean zero and variance  $\phi$ , on the scale of the linear predictor. The resulting distribution can be termed Poisson-Lognormal where the Log originates from the log link function. The RPLOGNORMAL procedure estimates the parameters of this model using Maximum Likelihood. The likelihood cannot be calculated analytically and therefore (adaptive) Gauss-Hermite integration is used. This is an approximate method which is sometimes inaccurate without

giving notice, see Lesaffre & Spiessens (2001). Numerical precision is generally increased by using adaptive Gauss-Hermite integration, see Liu & Pierce (1994). Note that the mean and variance of the Poisson-Lognormal distribution and the Negative Binomial distribution are the same so that alternatively a negative binomial regression model can be fitted.

A call to the RPLOGNORMAL procedure must be preceded by a MODEL statement with option settings DISTRIBUTION=poisson and LINK=logarithm. The user can also choose to set the WEIGHTS, OFFSET and GROUPS options of the MODEL directive.

The options and parameter of RPLOGNORMAL are similar in many ways to the standard regression directives. There is a single parameter TERMS to define the model terms to be fitted, and the first four options, PRINT, CONSTANT, FACTORIAL, and NOMESSAGE, all have the same syntax and purpose as in FIT. The FULL option has the same purpose as in TERMS. The warning setting of NOMESSAGE suppresses warnings messages concerning the iterative fitting algorithm.

The number of Gauss-Hermite integration points can be specified by the NPOINTS option. It is advised to use sufficient integration points especially when the dispersion parameter is large. Setting ADAPTIVE to the default value yes will generally increase numerical precision. The model is fitted by an iterative process as specified by the METHOD option using either a form of Newton-Raphson or a form of Golden Section Search. The MAXCYCLE option specifies the number of iterations, and the TOLERANCE option defines the convergence criterion. Initial values for the overdispersion parameter  $\phi$  can be specified by means of the INITIAL option. Full details of the iterative procedure and the way in which the initial values are handled are given in the Method section. The iterative process can be monitored by specifying PRINT=monitoring; this will first display monitoring of the way in which an initial value for  $\phi$  is obtained, followed by monitoring of the iterative process itself. Alternatively, setting FIXPHI=yes will fit the model for a fixed value of the overdispersion parameter  $\phi$ ; the fixed value must then be specified by means of the PHI option.

A large number of options can be used to save results from the fitted model, most of which are similar to the RKEEP directive. Fitted values and leverage corrected Pearson residuals can be saved by means of the FITTEDVALUES and RESIDUALS options. The ESTIMATES, SE and VCOVARIANCE options save results for the regression parameters, while PHI and SEPHI save the estimate of the overdispersion parameter  $\phi$  and its standard error. Note that all standard errors and variances thus saved are corrected for the estimation of  $\phi$ . The full covariance matrix with covariances between the regression parameters and the dispersion parameter can be saved by means of the FULLVCOVARIANCE option. The value of minus twice the maximized log-likelihood and the corresponding degrees of freedom can be saved by means of the \_2LOGLIKELIHOOD and DF options. This may be useful to compare nested model employing a likelihood ratio test.

Additional results can be saved by setting the SAVE option. This will save, in a pointer, (1)  $\log(\phi)$ ; (2) the standard error of  $\log(\phi)$ ; (3) the linear predictor; (4) the leverage; (5) the iterative weights which includes the regression weights; (6) the adjusted response; (7) the standard errors of the linear predictor; (8) the score with the first order derivative of the log-likelihood with respect to the linear predictor; (9) the contribution of each unit to the value of minus twice the maximized log-likelihood; (10) the variance of the Logit-Normal distribution for every value of the linear predictor; (11) the conditional expectation of the mean given the observed value which is termed blup; (12) the number of cycles of the iterative procedure; (13) a logical value indicating non-convergence; three logical values indicating that the estimate of  $\phi$  is (14) close to a limit as specified by INITIAL, (15) equal to the lower bound 0.0001, (16) equal to the upper bound 1000.

## Method

For a fixed overdispersion parameter  $\phi$ , all parameters are linear and iteratively reweighted least squares (IRLS) can be used to maximize the log-likelihood (Stirling, 1984). The log-likelihood is intractable and (adaptive) Gauss-Hermite integration is used to approximate it.

The overdispersion parameter  $\phi$  can be estimated by the Newton-Raphson method to solve the score equation for  $\phi$  (for a fixed set of fitted values). The overdispersion parameter  $\phi$  is, by definition, positive and therefore the score equation for  $\log(\phi)$ , rather than  $\phi$  itself, is used. Alternating between the two processes, i.e. IRLS and Newton-Raphson, until convergence yields joint maximum likelihood estimates of

$\phi$  and the regression parameters. The iteration stops when the maximum relative change in likelihood contributions in successive iterations is less than the tolerance, or in case the iteration number exceeds 10, when the relative change in the value of minus twice the log-likelihood is less than the tolerance divided by 1000. This all is used by the METHOD settings `NewtonRaphson` and `N2ewtonRaphson`. These two methods only differ in the way an initial value for  $\phi$  is derived. The first method employs the `RNEGBINOMIAL` procedure to obtain a starting value for  $\phi$  and for the linear predictor. The second method first fits the model for a number of fixed values of  $\phi$  as set by the `INITIAL` option, and then interpolates to an initial value of  $\phi$  with minimal log-likelihood. This last method also uses the fact that the log-likelihood as a function of  $\phi$  is convex.

Alternatively the overdispersion parameter  $\phi$  is estimated by a form of Golden Section Search as implemented by the `FMINIMIZE` procedure. An initial bracketing interval is obtained by subsequently fitting the model for a number of fixed values of  $\phi$  as set by the `INITIAL` option. See `FMINIMIZE` for the convergence criterion.

For most datasets `METHOD=NewtonRaphson` will give maximum likelihood estimates in a limited number of iterations. Occasionally, e.g. due to a flat likelihood, this estimation method fails and then `METHOD=brent` provides a robust alternative.

The estimate of  $\phi$  is not asymptotically independent of the regression parameters, and so a corrected variance-covariance matrix is calculated by means of the method outlined in Stirling (1984). The variance-covariance matrices, and standard errors, use observed rather than expected information as there is no closed form available for expected information. A confidence interval for  $\phi$  can be calculated best on the log scale, and therefore  $\log(\phi)$  and its estimated standard error can be saved by means of the `SAVE` option. Note that the standard errors of the linear predictor are saved from the last IRLS fit and are thus **not** corrected for the estimation of  $\phi$ .

## Action with RESTRICT

Only the response variate can be restricted and the analysis is restricted accordingly.

## RPLS

P.W. Goedhart &amp; C.J.F. Ter Braak

Does regression by partial least squares with leave-out options

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	Printed output required ( <i>press</i> ); default <i>press</i>
NPLS = <i>scalar</i>	The maximum number of PLS dimensions to be fitted; default 5 or the number of predictors if smaller than 5
LEAVE = <i>scalar or factor</i>	Determines leave-out groups. If a scalar is specified, groups of size LEAVE are formed in a systematic way. For LEAVE=0 no units are left out; default 0, i.e. no units are left out
STORE = <i>scalar or variate</i>	Defines dimensions for which results are stored. If STORE is set to a variate, it must contain increasing values. For STORE=0 results are stored for dimensions 1 ... NPLS. If STORE=NPLS then VARBETA is a variance-covariance matrix; default 0

### Parameters

X = <i>pointers</i>	Pointer containing the predictor variables
RESIDUALS = <i>pointers</i>	Pointer to save variates with the residuals of the response variable for dimensions in STORE. Residuals are leave-out or resubstitution residuals depending on the way units are left out
PRESS = <i>variates</i>	To save the mean prediction sum of squares. PRESS is calculated over all units or, if LEAVE specifies two leave-out groups, over units in the second group
BETA = <i>pointers</i>	Pointer to save variates containing the regression coefficients or, if LEAVE specifies more than two leave-out groups, jackknife regression coefficients for dimensions in STORE
VARBETA = <i>pointers</i>	Pointer to save variates containing the jackknife variances of BETA or pointer to save a symmetric matrix containing the jackknife variance-covariance matrix of BETA, both for dimensions in STORE
CONSTANT = <i>pointers</i>	Pointer to save scalars containing the constant in the regression model for dimensions in STORE. BETA must be stored as well
COEFFICIENTS = <i>pointers</i>	Pointer to save variates containing the coefficients to calculate PLS-scores from the predictors, stored for dimensions 1 ... NPLS
MAHALANOBIS = <i>variates</i>	To save the Mahalanobis squared distance calculated with respect to NPLS scores. Distances are leave-out or resubstitution distances depending on the way units are left out

### Description

Procedure RPLS does regression by partial least squares (PLS). This procedure uses an external C# program. PLS is useful in regression problems with many predictors or when predictors show high collinearity. These problems typically occur in observational studies and in multivariate calibration. PLS is an improvement over the earlier method of principal components regression (PCR). PCR is a two-stage method. At the first stage principal components of the predictor variables are formed to account for most of the variation in the predictors while at the second stage the response variable is regressed on these principal components. In PLS the two stages are combined so as to yield large predictive power with fewer dimensions than PCR. PLS sequentially forms orthogonal linear combinations of predictor variables with weights proportional to their covariance with the response variable when fitting the first dimension, and with the residual of the response variable when fitting subsequent dimensions. A description of the PLS algorithm and further references are given in Næs, Irgens & Martens (1986).

A call to RPLS must be preceded by a MODEL statement in which the response variable is specified. Only the first response variable is analysed and the WEIGHTS, OFFSET and GROUPS options of MODEL, if

specified, are ignored for the PLS fit. Generalized models are not allowed. The number of PLS dimensions fitted is determined by option `NPLS` while the dimensions for which results are stored can be controlled by the `STORE` option. Option `LEAVE` defines the leave-out groups. If `LEAVE` is set to a scalar, say  $m$ , the first  $m$  units form the first group, the second  $m$  the second group, etc. `LEAVE` determines the way in which `RESIDUALS`, `BETA`, `CONSTANT`, `MAHALANOBIS` and `PRESS` are calculated. Three situations can be distinguished:

1. If `LEAVE=0` PLS is performed for all units and `BETA` and `CONSTANT` are calculated accordingly. `PRESS`, `RESIDUALS` and `MAHALANOBIS` are calculated by resubstitution.
2. If `LEAVE` is set to a factor with two levels or set to a scalar which defines two groups, the first group is taken as training set and the second as evaluation set. `BETA` and `CONSTANT` are calculated for the training set. `RESIDUALS` and `MAHALANOBIS` are calculated by resubstitution for the training set and by leave-out for units in the evaluation set. `PRESS` is calculated over units in the evaluation set only.
3. If `LEAVE` is set to a factor with more than two levels or set to a scalar defining more than 2 groups, then all results are calculated by means of leave-out. Every group is subsequently left out from the analysis and leave-out `RESIDUALS` and `MAHALANOBIS` are calculated. `PRESS` is calculated over all leave-out residuals. `BETA` stores the jackknife regression coefficients while `CONSTANT` is set to missing values. In this case jackknife variances of `BETA` can be stored by means of `VARBETA`. A jackknife variance-covariance matrix of `BETA` can be stored by setting `STORE` equal to `NPLS`; the only dimension stored is then `NPLS`.

The `COEFFICIENTS` can be used to calculate PLS-scores from the predictor variables (see example 2). `COEFFICIENTS` are based on all units in situation 1 and 3, and in situation 2 based on the training set only. `PRINT` controls the printing of `PRESS` and of the square root of `PRESS`.

## Method

The procedure passes the problem to a C# .NET Framework 3.5 program by using the `SUSPEND` directive. The PLS algorithm can be formulated in different ways. Næs et al. (1986) gives two algorithms, with and without orthogonal scores. However, both algorithms need a time consuming updating step. Wold et al. (1984) showed that PLS essentially is a conjugate gradient algorithm for linear least squares problems. From the available algorithms, reviewed by Paige and Saunders (1982), the CGLS algorithm appeared to be a good compromise between numerical accuracy and speed (required for leave-out methods). The CGLS algorithm is implemented in C# using double precision arithmetic throughout. Numerical inaccuracy is most likely to affect the statistically irrelevant dimensions only.

Variables are standardized to zero mean and unit sum of squares before calling CGLS; the results are backtransformed to the original scale. `RPLS` thus implements PLS with "auto scaling" of the predictor variables (Wold et al., 1984). When units are left out, variables are re-standardized for the remaining units.

The calculation of scores from `COEFFICIENTS` in GenStat is numerically unstable, especially for higher dimensions. The computation can be checked by comparing the residuals of the regression of the response variable on the scores with the residuals produced by `RPLS` (see example 2).

The Fortran routine performs several checks. If one of these checks fails a fault code with an explanatory message is printed and the rest of the job will be ignored.

## Action with RESTRICT

Only the response variate can be restricted. The analysis is restricted accordingly. The predictor variables and the leave-out factor must not be restricted. So if the leave-out factor only has two levels in the restricted set, the group with the first level is taken as the training set and the remaining units as the evaluation set. Parameters `RESIDUALS` and `MAHALANOBIS` are not restricted on output.

## RSELECT

P.W. Goedhart

Selects best subsets of predictor variables in regression

[contents](#) [previous](#) [next](#)

### Options

CRITERION = <i>string token</i>	Criterion for selecting best subsets ( <i>r2</i> , <i>adjusted</i> , <i>cp</i> ); default <i>r2</i>
CONSTANT = <i>string token</i>	How to treat the constant ( <i>estimate</i> , <i>omit</i> ); default <i>estimate</i>
PENALTY = <i>scalar</i>	Penalty in interval $(0, \infty)$ for Mallows $C_p$ ; default 2
NBESTMODELS = <i>scalar</i>	Number of subsets desired for each size of subset when CRITERION= <i>r2</i> (default 5), in total when CRITERION is set to <i>adjusted</i> or <i>cp</i> (default 30). The total number of subsets to be selected should not exceed 150
TOLERANCE = <i>scalar</i>	Minimum tolerance in order to exclude subsets that are collinear. The default value is $k^2 * 2^{*-}(-28)$ where <i>k</i> is the total number of FREE and COVARIATES predictors. A value less than the default is replaced by the default. The tolerance should be in the interval $[0, 1)$
NPRINT = <i>scalar</i>	The maximum size of subsets for which output is printed; default 30
MEANSQUARE = <i>scalar</i>	Mean square of residuals for calculation of $C_p$ . A value smaller than or equal to 0 is replaced by the mean square residual of the full model; default 0
FORCED = <i>formula</i>	Model formula that is fitted to the response variate before best subsets are selected
COVARIATES = <i>variates</i>	Predictor variables that should be included in each model
RESULTS = <i>pointer</i>	Pointer to save 5 variates containing the number of included predictors, the three criteria and the minimum tolerance for the selected subsets
TVALUES = <i>pointer</i>	Pointer to save variates containing the t-values of regression coefficients for the selected subsets. A missing value indicates that the corresponding predictor is not in the selected subset
SUBSETS = <i>pointer</i>	Pointer to save pointers with the selected subsets of predictor variables FREE and COVARIATES

### Parameters

FREE = <i>variates</i>	Predictor variables from which best subsets are selected
------------------------	--

### Description

This procedure uses an external C# program. There are various methods for choosing a regression model when there are many predictor variables, see e.g. Montgomery and Peck (1992). GenStat directive STEP, used in a FOR loop, provides forward selection, backward elimination and stepwise regression. However these methods result in only one model and alternative models, with an equivalent or even better fit, are easily overlooked. Moreover, in most applications the particular predictors that effect the response and the directions of their effects are of intrinsic interest and then selection of just one well-fitting model is unsatisfactory and possibly misleading. To overcome this, RSELECT evaluates all possible subsets of predictor variables and selects a small number of best subsets. RSELECT should be used with caution, especially when the number of predictors is large in comparison with the number of units. In this case uncritical use of RSELECT might lead to models which appear to have a lot of explanatory power, but contain noise variables only, see e.g. Flack and Chang (1987). Predictors should therefore not be selected on the basis of a statistical analysis alone.

Identification of the best subsets depends upon the criterion used for measuring goodness of fit. The three criteria employed in RSELECT are widely used and are defined as follows:

$R^2$	$100 * (1 - \text{RSS} / \text{SSY})$
Adjusted $R^2$	$100 * (1 - (n - 1) * \text{RSS} / (\text{SSY} * (n - p)))$
Mallows $C_p$	$\text{RSS} / \text{RMSFULL} + 2 * p - n$

in which

RSS	is the residual sum of squares for the subset at hand;
SSY	is the sum of squares about the mean of the response variate;
p	is the number of fitted parameters (including the intercept);
n	is the number of units;
RMSFULL	is the residual mean square for the full model.

When  $R^2$  is used as selection criterion, there is no penalty for adding a predictor.  $R^2$  always improves with the addition of a predictor. When adjusted  $R^2$  or  $C_p$  is employed, there is a penalty for adding a variable. Adjusted  $R^2$  improves when the F-ratio due to the addition of the predictor is larger than 1, while  $C_p$  improves when the F-ratio is larger than 2. Clearly,  $C_p$  is the more conservative criterion and will tend to select smaller subsets as compared to  $R^2$  and adjusted  $R^2$ . The definition of  $C_p$  can be altered by setting options PENALTY and MEANSQUARE, in which case

$$C_p = \text{RSS} / \text{MEANSQUARE} + \text{PENALTY} * p - n.$$

In this case  $C_p$  improves when the F-ratio is larger than PENALTY.

An advantage of using  $R^2$  as the selection criterion is that the best subsets within **each** size of subset are selected. In the case of adjusted  $R^2$  or  $C_p$  best subsets are selected regardless of the subset size. The CRITERION option controls which of the three criteria is used. The number of selected subsets is defined by the NBESTMODELS option, while the NPRINT option controls the maximum size of subset for which output is produced. Default is to print all selected subsets. The printed output of RSELECT is adjusted to the width of the output file. Output might not be transparent if the output width is too small.

Best subsets are selected subject to an optional constraint, set by the TOLERANCE option, on the degree of correlation permitted among the predictor variables of a subset. For this purpose the minimum tolerance of a subset is used. This is defined as 1 minus the maximum of all the multiple correlations between individual predictors in the subset and the remaining predictors in that subset. The minimum tolerance is thus a measure of the degree of multicollinearity in the subset with small values indicating collinearity. If the minimum tolerance for a subset is smaller than the setting of TOLERANCE, that subset is omitted and a message is printed. Subsets with small tolerances are often unstable and may perform poorly when they are used for prediction purposes. Therefore, if RSELECT only selects subsets with small tolerances, a deeper search can be forced by specifying a larger value for TOLERANCE.

A call to RSELECT must be preceded by a MODEL statement which defines the response variate and, if required, a vector of weights and an offset. The MODEL directive should not specify the GROUPS option. Only the first response variate is analysed and generalized linear regression models are not allowed. The FREE parameter specifies the list of predictors from which best subsets are selected according to the chosen criterion. For each selected subset the three criteria are printed along with the minimum tolerance and t-values of regression coefficients of included predictors. Negative values for the criteria are not printed and  $C_p$  is truncated at 999.99. In order to keep output concise, t-values are also truncated.

It is sometimes desirable to include some predictors in each model and to investigate whether other predictors should be added to the model. Predictors that must be included in each model can be specified by means of the FORCED or the COVARIATES option. The COVARIATES option should be set to a list of variates and t-values are printed for these predictors. Alternatively, the FORCED option can be set to any formula, FORCED may thus contain factors and interactions as well as variates. The FORCED formula is fitted first to the response variate and to the FREE and COVARIATES predictors and the procedure continues with the residuals from these regressions. Consequently, the minimum tolerance is calculated for predictor variables allowing for the FORCED formula. This implies that the minimum tolerance depends on whether a FORCED formula is used or not. Moreover, t-values for the parameters associated with the FORCED formula are not printed. Note that if NPRINT is smaller than or equal to the number of COVARIATES variates, no output is produced.

The FREE and COVARIATES list of variates and the FORCED formula should be mutually exclusive. The total number of FREE and COVARIATES predictors should not exceed 30. The CONSTANT option controls whether the constant parameter is included in the model.

Cases with one or more missing values in the response variate, weight vector or any term in the full model are excluded from the analysis. This implies that, when terms have missing values for different units, FIT used on a subset of terms may give different results than RSELECT.

Options RESULTS, TVALUES and SUBSETS allow saving of the output. The RESULTS option saves a pointer with 5 variates, containing the number of included predictors, the three criteria and the minimum tolerance for the selected subsets. The t-values of regression coefficients and the formulae of the selected subsets can be saved by means of parameters TVALUES and SUBSETS respectively. All selected models are saved regardless of the setting of NPRINT. The saved criteria and t-values are not truncated.

## Method

If a FORCED formula is specified, the response variate and FREE and COVARIATES predictors are regressed on the FORCED formula and the response variate and predictors are replaced by the residuals of these regressions. The full model, including all COVARIATES and FREE predictors, is then fitted in order to exclude aliased predictors from the analysis. The double precision regression work structure is saved using the FSSPM directive and passed to an external C# .NET Framework 3.5 program by using the SUSPEND directive. The C# program calls subroutine Screen (Ter Braak and Groeneveld, 1982) which was written in Fortran but ported to C#.

Screen is the 1981 double precision version of a branch and bound algorithm for subset selection developed by Furnival and Wilson. They claim that this version is twice as fast as the 1974 version (Furnival and Wilson, 1974), requires much less storage and handles problems with rank deficient data in a more satisfactory manner. The algorithm stores the largest discrepancy observed in the value of the selection criterion for a number of numerical consistency checks. RSELECT prints this discrepancy as an indication of the numerical accuracy of the algorithm. The criteria, minimum tolerance and t-values are returned to GenStat. If necessary, the criteria and t-values are adjusted to incorporate effects of the fitting of a FORCED formula, the minimum tolerance is not adjusted. The procedure itself deals mainly with checking of options and parameters and with input and output of the Fortran program.

## Action with RESTRICT

Only the response variate can be restricted. The analysis is restricted accordingly. The vector of weights, the offset and terms in FREE, FORCED and COVARIATES must not be restricted.

## RUNCERTAINTY

M.J.W. Jansen, J.C.M. Withagen &amp; J.T.N.M. Thissen

Calculates contributions of model inputs to the variance of a model output

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What to print (fullmodel, uncertainty); default fullmodel, uncertainty
PLOT = <i>string token</i>	Graphical output required (histogram); default *
CURVE = <i>string token</i>	Type of curve to be fitted (linear, spline); default linear
ESTIMATES = <i>variate</i>	To save regression coefficients of all x variates (for CURVE=linear)
BOTTOM% = <i>variate</i>	To save bottom marginal variances as percentage of the variance of the model output. Increase of percentage variance accounted for when an x structure is last to be added
TOP% = <i>variate</i>	To save top marginal variances as percentage of variance of the variance of the model output. Percentage variance accounted for when an x structure is the only one to be fitted
ADJUSTEDR2 = <i>scalar</i>	To save adjusted percentage of variance accounted for by all x variates

### Parameters

X = <i>pointers or variates</i>	Set of model inputs for which uncertainty contributions are to be calculated. If a pointer is specified it must only point to variates
DF = <i>scalars</i>	Effective degrees of freedom of the smoothing splines to fit for each x structure; default 2
FITTEDVALUES = <i>variates</i>	Variates to store the fitted values for each x structure when that input is the only one to be fitted

### Description

Procedure RUNCERTAINTY performs uncertainty analysis given (1) a sample of model inputs from a joint distribution representing the uncertainty about these inputs and (2) a corresponding sample of the model output studied. The model output, given its inputs, may have been produced by specialised modelling software. The procedure calculates the contributions to the variance of the model output from individual or pooled model inputs by means of regression. These contributions are expressed as percentages of the variance of the model output. The top marginal variance of a model input is calculated as the percentage of variance accounted for when that input is the only one to be fitted; it is an approximation of the correlation ratio. The bottom marginal variance of an input is calculated as the increase of variance accounted for when that input is the last to be added to all other inputs. The calculation is successful if the percentage of variance accounted for by all inputs is close to 100, since the analysis only accounts for that part of the variance of the output that is explained by the regression (thus interactions between inputs are not considered). See Jansen et al (2002) and Saltelli et al (2000) for a detailed account of uncertainty analysis.

A call to RUNCERTAINTY must be preceded by a MODEL statement which defines the response variate with the model outputs. Only the first response variate is analysed and options other than WEIGHTS should not be set in the MODEL statement. Generalized linear models are not allowed. The model inputs are specified by the X parameter that can consist of variates or pointers to one or more variates. If a pointer is specified the total contribution of the variates of the pointer is calculated. The calculation applies multiple linear regression or spline regression of Y on the X structures plus a constant term. The choice between linear and spline regression can be made by means of the CURVE option. When using CURVE=spline, the degrees of freedom of the smoothing spline can be set separately for each X structure by means of the DF parameter. On output the full model has been fitted, and RKEEP and RDISPLAY can be used to further store and display the fit of the full model.

Cases with one or more missing values in the response variate, weight vector or any term in the full model are excluded from the analysis. This implies that, when terms have missing values for different units, FIT used on a subset of model inputs may give different results than RUNCERTAINTY.

The option setting `PRINT=fullmodel` prints the fit of the full model while suppressing all warning messages. Setting `PRINT=uncertainty` prints the top and bottom marginal %variances of the `x` structures and, in case `CURVE=linear`, the parameter estimates of the full model. The option setting `PLOT=histogram` option draws a histogram of the top and bottom marginal %variances side by side for each of the `x` structures. The results of the uncertainty analysis can be saved by means of options `ESTIMATES` (in case `CURVE=linear`), `BOTTOM%`, `TOP%` and `ADJUSTEDR2`. The fitted values of the models with individual `x` structures only (pointers and/or variates) can be saved by means of the `FITTEDVALUES` parameter. These fittedvalues correspond to the top marginal %variances.

## Method

The procedure calculates the percentage of variance accounted for the relevant regressions. The top marginal %variance for an input `X` is calculated as  $100(\text{vary}-\text{rmstop})/\text{vary}$ , where `vary` is the variance of the response and `rmstop` is the residual mean square of the model with only input `X`. The bottom marginal %variance for an input `X` equals  $100(\text{rmsbottom}-\text{rmsall})/\text{vary}$ , where `rmsall` is the residual mean square of the full model with all inputs, and `rmsbottom` is the residual mean square of the full model without input `X`. A `TERMS` statement in the procedure deals with missing values in the `x` variates.

## Action with RESTRICT

Only the response variate can be restricted. The analysis is restricted accordingly. Restrictions on the `x` structures are not allowed. The saved `FITTEDVALUES` variates will be unrestricted, but only units not excluded by the restriction will have values.

## SETDEVICE

M.P. Boer, J.T.N.M. Thissen &amp; P.W. Goedhart

Opens a graphical file on the basis of a file extension

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	What to print ( <i>filename</i> ); default *
SURNAME = <i>text</i>	Surname of graphical file to open; default * uses the surname of the file on the current input channel
EXTENSION = <i>string token</i>	Extension of graphical file to create ( <i>bmp, pdf, eps, emf, jpeg, jpg, tif, tiff, png</i> or <i>gmf</i> ); default <i>png</i>
SUBDIRECTORY = <i>text</i>	Subdirectory below the directory of the file on the current input channel in which the graphical files will be opened; default * does not use a subdirectory
FIRSTNUMBER = <i>scalar</i>	First sequence number for the graphical file name; default 1
NDIGITS = <i>scalar</i>	Number of zeros with which the sequence number of the graphics file is padded; default 2
PALETTE = <i>string token</i>	How to represent colour ( <i>monotone, greyscale, grayscale, colour</i> ); default * uses the setting of a previous call to SETDEVICE or, when not already called, the <i>colour</i> setting
RESOLUTION = <i>scalar</i>	Specifies the height of the saved image in pixels; default * uses the setting of a previous call to SETDEVICE or, when not already called, the value 2000
ACTION2 = <i>string token</i>	How to create graphs ( <i>asynchronous, synchronous</i> ); default * uses the setting of a previous call to SETDEVICE or, when not already called, the value <i>synchronous</i>
SEQUENCERESET = <i>string token</i>	Whether to reset the sequence of graphical files ( <i>yes, no</i> ) default <i>no</i>
CREATEFILE = <i>scalar</i>	Logical expression indicating whether (1) or not (0) to create a new graphical file; default 1 creates a new graphics file
SAVEFILENAME = <i>text</i>	Saves the filename of the graphical file. This is only set to a new filename when the logical expression CREATEFILE is set to true

### Parameters

FILENAME = <i>texts</i>	Name of the graphical file including one of the possible extensions <i>.bmp, .pdf, .eps, .emf, .jpg, .jpeg, .tif, .tiff, .png</i> or <i>.gmf</i>
NUMBER = <i>scalars</i>	Saves the device number corresponding to the graphical format specified by parameter FILENAME or, if this is not set, by option setting EXTENSION
ACTION = <i>string token</i>	How to create graphs ( <i>asynchronous, synchronous</i> ); default <i>asynchronous</i>

### Description

Procedure SETDEVICE is an updated version of the procedure in the official GenStat Procedure Library. When the FILENAME parameter is set the procedure operates in the same way as the official procedure. When FILENAME is not set, the procedure enables automatic opening of a sequence of graphics files. In any case SETDEVICE closes all graphical files before a new graphical file is opened.

In case FILENAME is set all options except PALETTE and RESOLUTION are ignored and a graphical file is opened with that name. The ACTION parameter controls how graphs are created. The device number is set on the basis of the extension of the given filename and can be saved by means of the NUMBER parameter. The table below shows the correspondence between the file extension and the saved device number.

Extension	Device	Type of file
.bmp	2	Windows BitMaP file
.pdf	4	Adobe Portable Document Format file
.eps	5	Encapsulated PostScript file
.emf	6	Windows Enhanced Meta File
.jpg or .jpeg	7	JPEG file
.tif or .tiff	8	Tagged Image File Format file
.png	9	Portable Network Graphics file
.gmf	10	GenStat Meta File

For an explanation of the PALETTE and RESOLUTION options and the ACTION parameter, see the DEVICE directive.

When the FILENAME parameter is not specified, most option settings determine automatic opening and closing of a sequence of graphics files. In case the SURNAME option is not set, the directory and surname of the file on the current input channel will be used to name the graphics file which will be opened. In case the SURNAME option is set, the given surname and the working directory will be used. The directory can be appended by a subdirectory, one level deep only, as specified by the SUBDIRECTORY option. The filename is appended with '-', a sequence number and the EXTENSION option setting to give a new filename. The first sequence number is given by the setting of the FIRSTNUMBER option, and successive calls to SETDEVICE will update the sequence number. The NDIGITS option can be used to pad the sequence number with extra zeros. The corresponding graphics channel, according to the EXTENSION setting in the table above, is then closed and a new graphics file with the new filename is opened. The new graphics file will use the current settings of the PALETTE, RESOLUTION and ACTION2 option. The SEQUENCERESET option can be used to reset the sequence of filenames. Note that the option settings SURNAME, EXTENSION, SUBDIRECTORY, FIRSTNUMBER and NDIGITS are only relevant the first time SETDEVICE is called or when SEQUENCERESET=yes. In other cases the settings of a previous call to SETDEVICE are used. However the options settings of PALETTE, RESOLUTION and ACTION2 are relevant for every call to SETDEVICE, i.e. when these options are not set the settings of a previous call to SETDEVICE are used.

By default a new plot file is always created, but this can be suppressed by setting the CREATEFILE option to zero. This is especially convenient when multiple windows are used in a single graph, see for instance the example program. The filename can be saved by means of the SAVEFILENAME option; this will only be set to a new filename when the logical expression CREATEFILE is set to 1 (true).

By default the ACTION2 option is set to synchronous. This is especially convenient in combination with the DCROP procedure which crops white borders in graphical files. This is because synchronous ensures that all graphical information is written to the file before executing another command so that the graphical file is available for the DCROP procedure. Note that the default setting of the ACTION parameter is asynchronous to retain compatibility with the official SETDEVICE procedure.

The PRINT option can be used to print the graphical filename along with its RESOLUTION.

## Method

All graphical files are closed by SETDEVICE before a new graphical file is opened. A GenStat WORKSPACE with name 'BiometrisSetDevice' is used to save the current option settings between successive calls to the procedure.

## Action with RESTRICT

Not relevant.

## References

None.

## Procedures Used

SFILENAME, DIRLIST and QENQUIRE. It also uses the subsidiary procedure \_DKDEVICES which is called by the official SETDEVICE procedure.

## Similar Procedures

DCROP can used to crop white space for some of the graphical files.

## SFILENAME

P.W. Goedhart

Splits a filename, which is opened by GenStat or not, into substrings

[contents](#) [previous](#) [next](#)

### Options

INPUTNAME = <i>text</i>	Filename to split into substrings; default is to use the CHANNEL and FILETYPE parameters
CASE = <i>string token</i>	Case to use for output structures ( <i>given</i> , <i>lower</i> , <i>upper</i> , <i>changed</i> ); default <i>given</i> leaves the case of each letter as given in the original string

### Parameters

CHANNEL = <i>scalars</i>	Channel numbers for which the filenames must be retrieved; default 1
FILETYPE = <i>string tokens</i>	Type of each file ( <i>input</i> , <i>output</i> , <i>unformatted</i> , <i>backingstore</i> , <i>procedurelibrary</i> , <i>graphics</i> ); default <i>input</i>
OPEN = <i>scalars</i>	To indicate whether or not the corresponding channels are currently open (0=closed, 1=open)
NAME = <i>texts</i>	Saves the full name of the file, including the directory
DIRECTORY = <i>texts</i>	Saves the directory of the file, including the trailing slash
FILENAME = <i>texts</i>	Saves the name of the file, excluding the directory
SURNAME = <i>texts</i>	Saves the surname of the file, i.e. the name excluding the path, the period and the extension
EXTENSION = <i>texts</i>	Saves the extension of the file, excluding the leading period

### Description

Procedure SFILENAME can be used in two different ways. The first use is to ascertain whether a particular channel is already in use and, if so, the name of the attached file is split into substrings. The channel for which substrings of filenames are required must be specified by means of the parameters CHANNEL and FILETYPE; the other parameters save the required information in data structures of the appropriate type. Text structures are only saved when the channel is open.

The second use is to split the setting of the INPUTNAME option; in that case the NAME parameter equals INPUTNAME and the OPEN parameter is set to missing.

The CASE option enables you to change the case of the letters of the output texts. By default, CASE=*given* leaves the case of each letter as given in the existing text. To change all letters to upper case (or capitals) you can put CASE=*upper*, or CASE=*lower* to change all letters to lower case. Alternatively, CASE=*changed* puts lower-case letters into upper case, and upper-case letters into lower case.

### Method

The ENQUIRE directive is used to retrieve the OPEN and NAME parameters. The substrings are formed by text manipulation using CONCATENATE.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

None.

## Similar Procedures

QFILENAME returns a single filename selected by means of a file open box on screen.

### Example

```
CAPTION 'SFILENAME example' ; STYLE=meta

    PRINT [IPRINT=*] tMessage ; FIELD=1 ; JUSTIFICATION=left ENDIF
ENDFOR
TEXT filename ; 'D:\\Windows\\System32\\*.dll'
SFILENAME [INPUTNAME=filename] DIRECTORY=directory ; SURNAME=surname ; \
EXTENSION=extension
PRINT [ORIENTATION=across ; RLWIDTH=12] filename, directory, surname, \
extension ; JUSTIFICATION=left ; SKIP=4
```

## SPECIALFUNCTION

P.W. Goedhart

Calculates a number of special mathematical functions

[contents](#) [previous](#) [next](#)

### Options

None.

### Parameters

$x$ = numerical structure	Argument of special function
J0BESSEL = numerical structure	Saves the Bessel function of order 0 for arguments in $x$
J1BESSEL = numerical structure	Saves the Bessel function of order 1 for arguments in $x$
I0BESSEL = numerical structure	Saves the modified Bessel function of order 0 for arguments in $x$
I1BESSEL = numerical structure	Saves the modified Bessel function of order 1 for arguments in $x$
A1 = numerical structure	Saves the function $A_1(x)$ for arguments in $x$
A1INVERSE = numeric. structure	Saves the inverse of the function $A_1(x)$ for arguments in $x$
A1DERIVATIVE = numerical structure	Saves the first order derivative of the function $A_1(x)$ for arguments in $x$

### Description

Procedure SPECIALFUNCTION can be used to calculate the following special mathematical functions:

- the Bessel functions of order 0 and 1, notated by  $J_0(x)$  and  $J_1(x)$  respectively;
- the modified Bessel functions of order 0 and 1, notated by  $I_0(x)$  and  $I_1(x)$  respectively;
- the function  $A_1(x) = I_1(x) / I_0(x)$ , its inverse and its first order derivative.

The argument for the Bessel functions and for  $A_1(x)$  and its derivative must not be negative, while the argument for the inverse of  $A_1(x)$  must be in the interval  $[0,1)$ . For more information about the Bessel functions, see e.g. Abramowitz and Stegun (1964). The function  $A_1(x)$  is especially useful in the analysis of circular data, see Fisher (1993).

The parameter  $x$  of the SPECIALFUNCTION procedure defines the arguments of the functions, using the notation given above. The function values can be saved by means of the other parameters; these are redefined to match the size and type of  $x$ .

All parameters must be either scalars, variates, matrices, symmetric matrices, diagonal matrices or tables. Pparameters must also have the same type.

### Method

The (modified) Bessel functions employ algorithms described in Press *et al* (1992). The inverse of  $A_1(x)$  is calculated by means of linear interpolation by calculating  $A_1(x)$  for a suitable range of values  $x$  and using the fact that  $\text{Logit}(A_1(x))$  is almost linear in  $\text{Log}(x)$ .

### Action with RESTRICT

The arguments  $x$  can be restricted. The function values are restricted accordingly with missing values for units excluded by the restriction.

## SREPLACE

L.C.P. Keizer &amp; J.T.N.M. Thissen

Replaces (or removes) substrings from each string of a text structure

[contents](#) [previous](#) [next](#)

### Options

REMOVE = <i>text</i>	Text structure with substrings to be removed from each string of the OLDTEXT parameter; default a single space ' '
REPLACE = <i>text</i>	Text structure with substrings to be replaced in the positions of the substrings of the REMOVE text structure; default ' '
CASE = <i>string token</i>	Whether lower and upper case letters are to be regarded as identical when removing substrings (significant, ignored); default significant
CHANGE = <i>string token</i>	Whether the first or all occurrences must be replaced in each string (first, global); default global

### Parameters

OLDTEXT = <i>texts</i>	Text structure from which substrings will be replaced; must be set
NEWTEXT = <i>texts</i>	To save the modified text structure

### Description

Procedure SREPLACE can be used to replace or remove substrings from the strings of the OLDTEXT parameter. The modified text structure can be saved by means of the NEWTEXT parameter, or if NEWTEXT is not set the OLDTEXT structure will be overwritten by the modified one. The substrings to be removed from each string of OLDTEXT can be specified by the REMOVE option and the substrings to be replaced by the REPLACE option. If the REPLACE option is not set the substrings of REMOVE are removed and not replaced. The lengths of the REMOVE and REPLACE structures should be the same. The first value of REMOVE is replaced by the first value of REPLACE and so on. There is one exception: a vector-valued REMOVE text can be combined with a single-valued REPLACE text. Then each value of REMOVE is replaced by the value of REPLACE. The default settings of REMOVE and REPLACE are such that all spaces are removed from the strings of the OLDTEXT text structure.

The CASE option specifies whether lower and upper case letters are regarded as identical when replacing substrings. The CHANGE option specifies whether only the first occurrence in each string must be replaced or whether all occurrences must be replaced.

### Method

Directives TXPOSITION and CONCATENATE are used in a loop.

### Action with RESTRICT

If the OLDTEXT parameter is restricted, the NEWTEXT parameter is restricted in the same way. Values in units excluded by the restriction are not altered. Restrictions on REMOVE and REPLACE are ignored.

### References

None.

### Procedures Used

None.

### Similar Procedures

None.

**Example**

```
CAPTION 'SREPLACE example' ; STYLE=meta
TEXT    text ; VALUES=!t('Drs. Paul Keizer', 'Ir. Jac Thissen')
SREPLACE text ; new
PRINT   text, new ; FIELD=20,23
SREPLACE [CHANGE=first] text ; new
PRINT   text, new ; FIELD=20,23
SREPLACE [REMOVE=!t(Paul, Jac) ; REPLACE=!t('L.C.P.', 'J.T.N.M.')] text ; new
PRINT   text, new ; FIELD=20,23
SREPLACE [REMOVE=!t('drs. ', 'ir. ') ; CASE=ignore] text ; new
PRINT   text, new ; FIELD=20,23
SREPLACE [REMOVE=!t(a,e,i,u)] text ; new
PRINT   text, new ; FIELD=20,23
SREPLACE [REMOVE=!t(r,s) ; CHANGE=first] text ; new
PRINT   text, new ; FIELD=20,23
```

## SUMMARIZE

J.C.M. Withagen

Prints summary statistics for variates

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What characteristics to print (mean, sd, %cv, median, minimum, maximum, nmv, nvalues, nobervations, quantiles); default mean, sd, median, nmv, nvalues
PROPORTIONS = <i>numbers</i>	Proportions at which to calculate quantiles; default .10, .25, .50, .75, .90
REPRESENTATION = <i>string token</i>	Representation of values of summary statistics (exponential, standard); default exponential
SAVE = <i>pointer</i>	To save all summary statistics in a pointer

### Parameters

DATA = *numerical structures*      Data to summarize; must be set

### Description

Procedure SUMMARIZE calculates summary statistics for numerical structures (scalars, variates, factors, tables, matrices) as specified by the DATA parameter. The statistics to be calculated are indicated by the PRINT option. The summary is printed in a table with structure identifiers as rows and names of the summary statistics as columns. If PRINT=quantiles quantiles are calculated at the proportions specified by the PROPORTIONS option and printed in a separate table. By default values are printed in E-format. They can be printed in standard output format by the setting the REPRESENTATION option to standard. The SAVE option can be set to save all summary statistics, printed or not, in a pointer. This implies that PRINT=\* can be combined with setting the SAVE option.

### Method

The procedure uses standard GenStat directives.

### Action with RESTRICT

Any restriction on variates and factors will be applied to all calculations.

### References

None.

### Procedures Used

SUMMARIZE calls the subsidiary procedure %SUMMARIZE which is the original version of this procedure operating only on variate structures.

### Similar procedures

DESCRIBE saves and/or prints summary statistics for variates, but in a different format.

### Example

```
CAPTION 'SUMMARIZE example' ; STYLE=meta
CALCULATE data[1...5] = URAND(50697,4(0) ; 100)
SUMMARIZE [PRINT=#,quantiles ; REPRESENTATION=standard] data[ ]
```

## SYM2VARIATE

J.T.N.M. Thissen

Copies a symmetric matrix to a variate along with row and column information

[contents](#) [previous](#) [next](#)

### Options

METHOD = *string token* Which elements of the symmetric matrix to copy (offdiagonal, all); default offdiagonal

### Parameters

SYMMETRICMATRIX = <i>symmetric matrices</i>	Symmetric matrix to copy; must be set
VARIATE = <i>variates</i>	To save the values of the symmetric matrix; must be set
RLEVELS = <i>variates</i>	To save the row levels
CLEVELS = <i>variates</i>	To save the column levels
RLABELS = <i>texts</i>	To save the row labels
CLABELS = <i>texts</i>	To save the column labels
RNUMBERS = <i>variates</i>	To save the row ordinal numbers
CNUMBERS = <i>variates</i>	To save the column ordinal numbers

### Description

Procedure SYM2VARIATE copies the elements of a symmetric matrix into a variate. All elements are copied by employing METHOD=all, while the default setting METHOD=offdiagonal only copies the off-diagonal elements. The values are saved in the VARIATE parameter. The row and column information can be saved in 3 ways:

1. If the ROWS option of the symmetric matrix is set to a text structure, the RLABELS and CLABELS parameters contain the relevant elements of this text and the RLEVELS and CLEVELS contain the numbers 1 till the dimension of the symmetric matrix.
2. If the ROWS option of the symmetric matrix is set to a variate, the RLABELS and CLABELS parameters contain the relevant elements of this variate as strings and the RLEVELS and CLEVELS contain the same values as numbers in a variate.
3. If the ROWS option of the symmetric matrix is set to a scalar, the RLABELS and CLABELS parameters contain the numbers 1 till this scalar as strings and the RLEVELS and CLEVELS contain the numbers 1 till the dimension of the symmetric matrix.

The RNUMBERS and CNUMBERS parameters always contain the numbers 1 till the dimension of the symmetric matrix.

### Method

The procedure uses standard GenStat directives.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

None.

### Similar procedures

None.

## TPOWER

P.W. Goedhart &amp; M.J.W. Jansen

Calculates and plots the power of Student's difference and equivalence t-tests

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string tokens</i>	What to print (description, power); default description, power
POWERCURVE = <i>string tokens</i>	Power curve to plot (none, effect, nreplicates); default none
DESIGN = <i>string token</i>	Designed experiment for which power must be calculated (random, block, latinsquare, onesample, general); default random
VARIANCE = <i>scalar</i>	Estimate of unit variance; default 1
NTREATMENTS = <i>scalar</i>	Number of treatments in a designed experiment; default 2
METHOD = <i>string token</i>	Type of test required (onesided, twosided); default twosided
TEST = <i>string token</i>	Which test to perform (difference, equivalence); default difference
LOWER = <i>scalar</i>	Lower limit for equivalence testing; default *, i.e. not set
UPPER = <i>scalar</i>	Upper limit for equivalence testing; default *, i.e. not set
PROBABILITY = <i>scalar</i>	Significance level at which the effect is required to be detected; default 0.05
ADFCONSTANT = <i>scalar</i>	Constant for residual degrees of freedom of a general design; default *
BDFCONSTANT = <i>scalar</i>	Constant for residual degrees of freedom of a general design; default *
CVAREFFECT = <i>scalar</i>	Constant for the variance of the effect for a general design; default *
DVARCONSTANT = <i>scalar</i>	Constant for the variance of the effect for a general design; default 0
ANNOTATION = <i>string tokens</i>	Defines the annotation of the power curves (description, curves, lines, grid); default description, curves, lines
LINESATPOWER = <i>scalars</i>	Power values for which horizontal lines are added to the plotted power curves, along with vertical lines at intersections with the power curves; default 0.9
WINDOW = <i>scalars</i>	Window numbers for the power curves for effect and/or nreplicates respectively; default * uses a full screen window
SCREEN = <i>string token</i>	Whether to clear the screen before plotting both power curves or to continue plotting on the old screen (clear, keep); default clear
TITLE = <i>texts</i>	General titles of the power curves for effect and/or nreplicates respectively; default * uses default titles
YTITLE = <i>texts</i>	Titles for the y-axis of the power curves for effect and/or nreplicates respectively; default 'Power'
XTITLE = <i>texts</i>	Titles for the x-axis of the power curves for effect and/or nreplicates respectively; default * uses default titles
PDESCRIPTION = <i>string tokens</i>	Position of description box in plot (tl, tc, tr, cl, cc, cr, bl, bc, br); default br, i.e. bottom right
SETTINGS = <i>variate</i>	Defines the settings for the calculation of the power of twosided equivalence tests. The three elements define the relative error tolerance, the absolute error tolerance and the maximum number of function values; default !(0.001, 0, 100000)

### Parameters

EFFECTS = <i>variates or scalars</i>	Effects for which the power has to be calculated; must be set
NREPLICATES = <i>variates or scalars</i>	Number of replicates for which the power must be calculated; must be set
POWER = <i>tables</i>	Saves the power of Student's t-test
SAVE = <i>pointers</i>	Saves variates which are used in the calculation of the power; also saves an estimate of the absolute error for twosided equivalence tests

## Description

Procedure TPOWER can be used to calculate the power of Student's difference and equivalence t-tests for some standard experimental designs and also in the general case. The EFFECTS and NREPLICATES parameters specify the effects and the number of replicates for which the power must be calculated. The procedure calculates the power for all combinations of the values in EFFECTS and NREPLICATES. The two-way table with power values can be printed by setting the PRINT option, or saved by means of the POWER parameter. Graphs with power curves can be requested by setting the POWERCURVE option.

The DESIGN option specifies which experimental design is used. The following designs are available:

- random            a completely randomized experiment with equally replicated treatments; the values in NREPLICATES are the number of replications of each treatment;
- block             a randomized complete block experiment; the values in NREPLICATES are the number of blocks;
- latinsquare      a set of latin squares; the values in NREPLICATES are the number of squares;
- onesample        a random sample with only one treatment; the values in NREPLICATES are the sample sizes;
- general            general design; see below.

The VARIANCE option must be set to the variability of units with the same treatment; this will in general be set to the residual mean square of a previous analysis of the same kind. The NTREATMENTS option specifies the number of treatments for the random, block and latinsquare designs. By default the number of treatments is set to two, which gives a two-sample t-test for DESIGN=random, a pairwise t-test for DESIGN=block and 2 x 2 latin squares for DESIGN=latinsquare. The METHOD option specifies whether the t-test is one-sided or two-sided. The significance level  $\alpha$  of the test must be specified by the PROBABILITY option.

The power for more general setups can be obtained by specifying DESIGN=general, in which case the ADFCONSTANT, BDFCONSTANT, CVAREFFECT and DVARCONSTANT options define the properties of the t-test. The degrees of freedom (dfresidual) of the residual variance, and the variance (vareffect) of the estimated effects are then defined by:

$$\text{dfresidual} = \text{ADFCONSTANT} * \text{NREPLICATES} - \text{BDFCONSTANT}.$$

$$\text{vareffect} = \text{DVARCONSTANT} + \text{CVAREFFECT} * \text{VARIANCE} / \text{NREPLICATES}$$

For the standard designs the baseline variance DVARCONSTANT equals zero and the other constants are defined as follows, where  $k$  is the number of treatments:

- |               |                              |                      |                   |
|---------------|------------------------------|----------------------|-------------------|
| - random      | ADFCONSTANT= $k$ ;           | BDFCONSTANT= $k$ ;   | CVAREFFECT= $2$   |
| - block       | ADFCONSTANT= $k-1$ ;         | BDFCONSTANT= $k-1$ ; | CVAREFFECT= $2$   |
| - latinsquare | ADFCONSTANT= $(k-1)*(k-1)$ ; | BDFCONSTANT= $k-1$ ; | CVAREFFECT= $2/k$ |
| - onesample   | ADFCONSTANT= $1$ ;           | BDFCONSTANT= $1$ ;   | CVAREFFECT= $1$   |

Note that the interpretation of the NREPLICATES values depends on the settings of the design constants. The setting of the NTREATMENTS option is discarded for the general case. The example program lists a number of general designs.

The power can be calculated for a difference or for an equivalence test as specified by means of the TEST option. A twosided difference test tests the null hypothesis that the effect  $e$  equals zero, i.e.  $H_0: e = 0$ , while a onesided difference test employs  $H_0: e \leq 0$ . In the latter case only positive effect sizes are of interest. The null hypothesis of a twosided equivalence test states that the effect is outside some interval  $[L, U]$ , i.e.  $H_0: (e \leq L \text{ and } e \geq U)$ . The alternative is called equivalence i.e.  $H_1: (L < e < U)$ . Two-one-sided t-tests are commonly employed to test this which is also known as the TOST approach (Schuirmann, 1987). Note that this implies that  $H_0$  is rejected when the  $(1-2\alpha)$  confidence interval for the effect lies completely in the interval  $[L,U]$ . This requires setting of a lower and upper limit by means of the LOWER and UPPER options. One sided equivalence test can be obtained by not setting either of these equivalence limits. For twosided equivalence tests the power is calculated by means of an external Fortran routine. In that case the SETTINGS option specifies the settings of the algorithm.

The POWERCURVE option can be set to request two types of powercurves. This is only useful for small number of values in the EFFECTS and NREPLICATES parameters. POWERCURVE=effect produces a graph with power curves as a function of the required effect, separately for every value in the NREPLICATES parameter. The effect ranges from the minimum to the maximum of the EFFECTS parameter, with a zero

effect added. POWERCURVE=nreplicates plots power curves as a function of the number of replicates, now separately for every value in the EFFECTS parameter. The nreplicates ranges from the minimum to the maximum of the NREPLICATES parameter. The ANNOTATION option defines the annotation of the powercurves: description displays an informative box, curves adds annotation to the curves, lines displays horizontal (and accompanying vertical lines) at power values specified by the LINESATPOWER option, and grid displays gridlines. Window settings and titles for both graphs, i.e. for effect and/or nreplicates power curves respectively, can be specified by setting options WINDOW, SCREEN, TITLE, YTITLE and XTITLE. Furthermore the position of the description box is set by the PDESCRIPTION option which uses abbreviations for top/centre/bottom and left/centre/right. These 6 options can be set to two values, the first setting is for the effect curve, the second for the nreplicates curve. Pen number 1 is used for the curves, pen 107 for the description and pen 213 for annotation of the curves. Pen numbers 2,3... are used for the lines as specified by the LINESATPOWER option. The axis labels and titles and the general title can be controlled by the default negative pen numbers.

The calculated power can be saved by means of the POWER parameter. The SAVE parameter can be employed to save variates which are used in the calculation of the power. This also saves an estimate of the absolute error for twosided equivalence tests.

## Method

The TPOWER procedure employs the non-central t-distribution. The basic calculations for a difference test are as follows:

```

CALCULATE dfres = ADFCONSTANT*NREPLICATES - BDFCONSTANT
CALCULATE vareffect = DVARCONSTANT + CVAREFFECT*VARIANCE/NREPLICATES
CALCULATE noncentral = EFFECTS/SQRT(vareffect)
IF (METHOD.EQS.'onesided')
  CALCULATE tval = EDT(1 - PROBABILITY ; dfres)
  CALCULATE POWER = CUT( tval ; dfres ; noncentral)
ELSE
  CALCULATE tval = EDT(1 - PROBABILITY/2 ; dfres)
  CALCULATE POWER = CUT( tval ; dfres ; noncentral) + \
                    CLT(-tval ; dfres ; noncentral)
ENDIF

```

For the onesided equivalence test similar statements employ the equivalence limits to calculate the non-centrality parameter of the t-distribution. In case only the lower equivalence limit is set:

```

CALCULATE tval = EDT(1 - PROBABILITY ; dfres)
CALCULATE lowerNC = (teffect-LOWER)/SQRT(vareffect)
CALCULATE POWER = CUT( tvalue ; dfres ; lowerNC)

```

and in case only the upper equivalence limit is set:

```

CALCULATE upperNC = (teffect-UPPER)/SQRT(vareffect)
CALCULATE POWER = CLT(-tvalue ; dfres ; upperNC)

```

For the twosided equivalence test the power is given by the probability that  $P((TL \geq tval) \text{ and } (TU \leq -tval))$  where  $(TL, TU)$  follows a bivariate noncentral t distribution with non-centrality parameters lowerNC and upperNC as given above, and a correlation between  $TL$  and  $TU$  which equals one. This problem is passed to an external C# .NET Framework 3.5 program by using the SUSPEND directive. This then employs Fortran subroutine MVTDST (Genz, 2013) which implements an algorithm for computing non-central multivariate t probabilities (Genz and Bretz, 2002). The copyright notice for using MVTDST can be retrieved by extracting the source code of the TPOWER procedure by means of the BIOMETRIS procedure.

Notably for small number of replicates the calculation of the tail probabilities of the non-central t-distribution may not converge, and the CUT and CLT functions return a zero value. Non convergence results in a fault code CA 58, in which case all zero power values are replaced by missing values. Power curves with one or more missing values, again due to non convergence, are not plotted.

## Action with RESTRICT

Restrictions on the EFFECTS and NREPLICATES parameters are taken into account.

## TSQUEEZE

L.C.P. Keizer &amp; J.T.N.M. Thissen

Squeezes a table to fewer levels of the classifying factors

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	What information to print ( <i>newtable</i> ); default *
MINIMUM = <i>scalar</i>	Minimum value for the values of <i>TABLE</i> ; default 0
MAXIMUM = <i>scalar</i>	Maximum value for the values of <i>TABLE</i> ; default *

### Parameters

TABLE = <i>tables</i>	Table without margins which should be squeezed; must be set
NEWTABLE = <i>tables</i>	To save the squeezed <i>TABLE</i>
SIMILARTABLES = <i>pointers</i>	Tables, which should be squeezed in the same way as <i>TABLE</i>
NEWSIMILARTABLES = <i>pointers</i>	To save the squeezed <i>SIMILARTABLES</i>

### Description

Procedure TSQUEEZE can be used to display or save a table with fewer levels of the classifying factors. The table should not have margins. By default those levels of the classifying factors of the *TABLE* parameter are removed that only have missing values or values less than or equal to zero in all corresponding cells. The *MINIMUM* and *MAXIMUM* options can be used to reduce or expand the range of values. Levels of factors with all values in the *TABLE* parameter less than or equal to *MINIMUM* or all values greater than *MAXIMUM* are then removed.

The squeezed table can be saved in the *NEWTABLE* parameter. When there are more tables that must be squeezed in the same way as *TABLE* they can be set by the *SIMILARTABLES* parameter. The new squeezed tables can be saved then in the *NEWSIMILARTABLES* pointer. The setting *PRINT=newtable* prints the squeezed table. The names of the classifying factors of the squeezed tables are formed from those of the original tables; For example, if the original table has a classifying factor “name”, the squeezed table has a classifying factor “\_name\_”.

### Method

The *COMBINE* directive is used to squeeze the tables.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

SUBSET and FPOINTER.

### Similar Procedures

None.

**Example**

```
CAPTION 'TSQUEEZE example' ; STYLE=meta
FACTOR [NVALUES=100 ; LEVELS=4] f1
FACTOR [NVALUES=100 ; LEVELS=5] f2
GENERATE f1, 5, f2
CALCULATE initialize = URAND(90124 ; 1)
CALCULATE x = GRNORMAL(100 ; 10 ; 8)
TABULATE [CLASSIFICATION=f1, f2] x ; MEAN=mean ; VARIANCE=var
PRINT [SERIAL=yes] mean, var
TSQUEEZE [MINIMUM=11] TABLE=mean ; NEWTABLE=newmean ; \
SIMILAR=!p(var) ; NEWSIMILAR=!p(newvar)
PRINT [SERIAL=yes] newmean, newvar
V2TABLE [CLASSIFICATION=newf1,newf2] newmean,newvar ; VARIATE=vmean,vvar
PRINT newf1, newf2, vmean, vvar
```

## V2TABLE

P.W. Goedhart

Forms a variate and a set of classifying factors from a table

[contents](#) [previous](#) [next](#)

### Options

CLASSIFICATION = <i>factors</i>	To save the (ordered) classifying set of the table; default *
MODIFY = <i>string token</i>	Whether to modify the classifying factors of the table (no, yes); MODIFY is only relevant when the CLASSIFICATION option is unset; default no

### Parameters

TABLE = <i>tables</i>	Tables to be copied
VARIATE = <i>variates</i>	To save the body of each table

### Description

Procedure V2TABLE can be used to store the body of a table in a variate and obtain a set of factors to represent the way in which the data are arranged in the table. These factors are then of the same length as the newly formed variate and classify the variate in the same way as in the table. Margins of the table are ignored.

The tables to be copied are specified by the TABLE parameter, the variates to receive the body of the tables must be specified by means the VARIATE parameter. The tables should have the same classifying factors. The DECIMALS and EXTRA attributes of the tables are transferred to the variates.

The CLASSIFICATION option can be used to obtain the (ordered) classifying factors of the first table. The newly formed factors have the same attributes as the classifying factors of the table. Alternatively, if the CLASSIFICATION option is unset or set to \*, the option setting MODIFY=yes can be used to shorten the classifying factors of the table so that they classify the newly formed variate.

Note that the order in which the factors are obtained can be unexpected for implicitly declared tables. To avoid confusion, the list of factors as specified by the CLASSIFICATION option, is compared with the list of ordered classifying factors of the table. If one or more factors in the ordered classifying list are in the CLASSIFICATION list, there position in these lists should be the same. If this is not the case a fault is generated. For example, the following lines will produce a fault message:

```
TABLE [CLASSIFICATION=f1, f2 ; VALUES=1,2,3,4] table
V2TABLE [CLASSIFICATION=f2, f1] table ; variate
```

### Method

To ensure that all tables have the same ordered classifying set, the tables are first copied to tables with the ordered classifying set of the first table. Margins of the table are then deleted by the MARGIN directive and the tables are equated to variates. The initial declarations of the new factors are done with DUPLICATE. Factor values are produced by GENERATE.

### Action with RESTRICT

Not relevant.

### References

None.

### Procedures Used

V2TABLE calls the subsidiary procedure %V2TABLECHECK which checks that the tables have the same classifying factors.

## Similar Procedures

VTABLE from the official GenStat Procedure Library can be used for tables with different classification sets.

# VSEARCH

P.W. Goedhart

Helps search through models for a generalized linear mixed model (GLMM)

[contents](#) [previous](#) [next](#)

## Options

PRINT = <i>string tokens</i>	What output to display (terms, details, changes, model, components, waldtests); default details, changes, model, components, waldtests
DISTRIBUTION = <i>string token</i>	Error distribution (normal, binomial, poisson, gamma, negativebinomial); default normal
LINK = <i>string token</i>	Link function (identity, logarithm, logit, reciprocal, probit, complementaryloglog, logratio); default * gives the canonical link
DISPERSION = <i>scalar</i>	Value at which to fix the residual variance, if missing the variance is estimated; default 1
RANDOM = <i>formula</i>	Random model excluding bottom stratum; this must be set
FREE = <i>formula</i>	Model formula specifying the candidate fixed model terms; this must be set
STARTFREE = <i>formula</i>	Model formula specifying the candidate fixed model terms with which to start the stepwise procedure; default * starts with an empty model
FORCED = <i>formula</i>	Fixed model formula to include in each model; default *
ADDPROBABILITY = <i>scalar</i>	p-value of significance test for adding candidate model terms; default 0.05
DROPPROBABILITY = <i>scalar</i>	p-value of significance test for dropping of candidate model terms; default 0.05
MAXSTEPS = <i>scalar</i>	Number of times the main stepwise loop is executed; default 1000
REPEAT = <i>string tokens</i>	Whether to repeat dropping or adding model terms within the main stepwise loop (drop, add); default * does not repeat either
PMETHOD = <i>string token</i>	How p values are calculated (chisquared, fdistribution); default fdistribution
SELECTEDMODEL = <i>formula</i>	Saves the selected model
GLMMINITIAL = <i>string token</i>	Whether to use initial fitted values from a previous model fit in the model sequence or not (yes, no); default yes
CONSTANT = <i>string token</i>	Whether to estimate or omit the constant term in the fixed model (omit, estimate); default estimate
FACTORIAL = <i>scalar</i>	Limit for expansion of fixed model terms; default 3
MAXCYCLE = <i>scalar</i>	Maximum number of iterations of the GLMM algorithm; default 20
TOLERANCE = <i>scalar</i>	Convergence criterion for the iterative GLMM algorithm; default 0.0001
FMETHOD = <i>string token</i>	Specifies fitting method (all, fixed): all indicates the method of Schall (1991); fixed indicates the marginal method of Breslow & Clayton (1993); default all
OFFSET = <i>variate</i>	Offset variate to be included in the fixed model; default *
CADJUST = <i>string token</i>	What adjustment to make to covariates for the REML analysis (mean, none); default mean
AGGREGATION = <i>scalar</i>	Fixed parameter for negative binomial distribution (parameter k as in variance function $\text{var} = \mu + \mu^2/k$ ); default 1
KLOGRATIO = <i>scalar</i>	Parameter k for logratio link, in form $\log(\mu / (\mu + k))$ ; default as set in AGGREGATION option
OWNDIST = <i>text</i>	For non-standard distributions: text specifying the variance function to be used with dummy variable DUM, e.g. OWNDIST= 'DUM'
OWNLINK = <i>text</i>	For non-standard link functions: text specifying 3 functions using dummy variable DUM - the link function, its inverse and its derivative,

	e.g. OWNLINK = !T('log(DUM)', 'exp(DUM)', '1/DUM')
CDEFINITIONS = <i>text</i>	Statements to execute to define correlation models; default * i.e. none
CVECTORS = <i>pointer</i>	Data structures involved in the correlation models
WORKSPACE = <i>scalar</i>	Number of blocks of internal memory to be set up for use by the REML algorithm; default 1

## Parameters

Y = <i>variates</i>	Response variates
NBINOMIAL = <i>scalars</i> or <i>variates</i>	Number of binomial trials for each unit (must be set if DISTRIBUTION=binomial)

## Description

VSEARCH can be used to perform stepwise selection of fixed model terms in a generalized linear mixed model by employing the GLMM procedure. Most of the options and parameters of the VSEARCH procedure originate from the GLMM procedure. The options specific to VSEARCH are FREE, STARTFREE, FORCED, ADDPROBABILITY, DROPPROBABILITY, MAXSTEPS, REPEAT, PMETHOD, SELECTEDMODEL and GLMMINITIAL.

The FREE option specifies the candidate model terms. These may include variates, factors and interactions. It is sometimes desirable to include specific terms in each model. Such terms may be specified by means of the FORCED option. If the FREE formula specifies a main effects model, i.e. a model without interactions, all main effects are the candidate terms. When the FREE formula contains interactions, first all terms marginal to an interaction are dropped from the FREE formula and are added to the FORCED formula. This ensures that the principle of marginality is never violated when the candidate terms are fitted in turn. The STARTFREE option specifies the candidate model terms with which to start the selection procedure.

Each iteration of the stepwise procedure consists of two parts. In the first part it is tested whether any of the current model terms can be dropped. This is done by fitting the current model and obtaining significance tests for all candidate terms in the current model. If the maximum p-value of these significance tests exceeds the value of the DROPPROBABILITY option, then the corresponding model term is dropped from the current model. In the second part it is tested whether any of the candidate model terms which are not in the current model can be added. This is done by adding these terms to the current model and obtaining a significance test. Note that these are single additions to the current model. If the minimum p-value of these tests is smaller than the value of the ADDPROBABILITY option, then the corresponding model term is added to the current model. After these two parts, the next iteration of the stepwise procedure starts. By specifying REPEAT=drop the first part itself is executed in a loop until no further terms can be dropped; after this loop the second part is executed. Likewise REPEAT=add involves repeated addition of model terms in the second part before any terms can be dropped.

Note that forward selection, i.e. no terms are ever dropped from the model, can be requested by setting the DROPPROBABILITY option to 1. Likewise backward elimination, i.e. no terms are ever added to the model, is obtained by specifying ADDPROBABILITY=0. In the latter case the STARTFREE and FREE options should be set to the same model formula.

The PMETHOD option controls how p-values are calculated for the significance tests. The significance test is always based on the Wald statistic. PMETHOD=chisquared calculates the p-value according to the chi-squared distribution. Alternatively PMETHOD=fdistribution employs the F statistic, which is the Wald statistic divided by its degrees of freedom. The p-value is then calculated with the F distribution with approximate denominator degrees of freedom as obtained by setting FMETHOD=auto of VKEEP. In case the denominator degrees of freedom is not available the chi-squared distribution is used. Note that in both cases the F statistic is printed.

The GLMMINITIAL option controls whether the INITIALVALUES parameter of the GLMM procedure is set to fitted values from a previous model fit. Setting this option to yes reduces running time but can occasionally result in a failure of the GLMM algorithm to reach convergence

Output is controlled by the PRINT option. The changes setting lists all the changes made to the model, while the details setting prints the sorted significance tests in each step of the stepwise procedure. Note

that estimates and standard errors are printed for effects with one degree of freedom; these should be interpreted with care as they are specific for the model that is current. The `terms` setting prints the forced and free terms which are used in the stepwise selection. The other `PRINT` settings, i.e. `model`, `components` and `waldtests`, can be used to display results for the selected model. `VDISPLAY` and `VKEEP` can also be used after procedure `VSEARCH` to redisplay or store other results for the selected model.

The response variate is specified using the `Y` parameter. The `NBINOMIAL` parameter must be set when `DISTRIBUTION=binomial` to specify the total number of trials on each unit, as a variate if the number varies from unit to unit or as a scalar if it is constant over all the units.

All other options are directly passed to the `GLMM` procedure; consult the description of `GLMM` for a full explanation. The `DISTRIBUTION` option sets the error distribution; the default is to assume a normal distribution but the binomial, poisson, gamma and negative-binomial distributions are also available. The link can be set using the `LINK` option; the default takes the canonical link. Other distributions and links can be employed by setting the `OWNDIST` and `OWNLINK` options. The `AGGREGATION` option supplies the aggregation parameter for the negative-binomial distribution, which is 1 by default. The `KLOGRATIO` option supplies the parameter  $k$  to be used in the logratio link, and takes its default from `AGGREGATION`.

The random model is specified by the `RANDOM` option. The dispersion parameter is assumed to be 1 unless otherwise specified by the `DISPERSION` option. Setting `DISPERSION=*` requests that the dispersion parameter be estimated. It is also possible to define correlation models on the random terms, although the results should be used with caution as their properties are not yet well understood. To do this, you should set the `CDEFINITIONS` and `CVECTORS` options as is explained in the description of the `GLMM` procedure.

The number of identifiers in free and forced terms can be limited using the `FACTORIAL` option. By default, a constant term is included in the model; this can be suppressed by setting option `CONSTANT=omit`. An offset can be included in the linear predictor by setting option `OFFSET`. By default all covariates are centred by subtracting their means, weighted according to the iterative weights of the generalized linear model. You can set option `CADJUST=none` to request that the uncentred covariates are used instead.

The `FMETHOD` option specifies the method used to form the fitted values and therefore determines the fitting method to be used. The default setting `all` specifies the penalized quasi likelihood method which is a subject specific model (Schall, 1991), while setting `fixed` requestst the marginal quasi likelihood method; see Breslow & Clayton (1993). Some control over the iterative `GLMM` algorithm is provided by option `MAXCYCLE` which sets the maximum number of iterations (default 20), and by option `TOLERANCE` which specifies the criterion for determining convergence of the algorithm (default 0.0001). The `WORKSPACE` option (default 1) specifies the number of blocks of internal memory to be allocated by the `REML` directive.

## Method

`VSEARCH` repeatedly calls the `GLMM` procedure to obtain significance tests for fixed terms to drop or add. Any warning or message diagnostics produced by the `GLMM` procedure are suppressed, except when fitting the selected model. The stepwise selection process can result in an indefinite loop, e.g. when a term has a p-value of 0.07 with `ADDPROBABILITY=0.10` and `DROPPROBABILITY=0.05`. This is detected by the procedure in which case the main loop is exited.

## Action with RESTRICT

Only the response variate can be restricted. The analysis is restricted accordingly. Identifiers in the fixed and random formulae must not be restricted and must not contain missing values.

## References

## Procedures Used

The subsidiary procedure `_RSEARCHCHECK` checks all the identifiers which are involved in the model. The generalized linear mixed models are fitted using the `GLMM` procedure and test statistics are obtained with the `VWALD` procedure.

## Similar Procedures

`RSEARCH` helps search through models for a regression or generalized linear model. `RSELECT` selects best predictor variables in ordinary linear regression.

## Example

```
CAPTION 'VSEARCH example' ; STYLE=meta
BIOMETRIS 'VSEARCH' ; DATA=DataVsearch
EXECUTE DataVsearch
POINTER [VALUES=age, xero, cosine, sine, female, height, stunted] free
VSEARCH [DISTRIBUTION=binomial ; RANDOM=child ; FREE=free[]] \
resp ; NBINOMIAL=1
VSEARCH [DISTRIBUTION=binomial ; RANDOM=child ; FREE=free[] ; \
STARTFREE=free[] ; REPEAT=drop] resp ; NBINOMIAL=1
VSEARCH [DISTRIBUTION=binomial ; RANDOM=child ; FACTORIAL=2 ; \
FREE=free[] + age*cosine*sine*height*stunted] resp ; NBINOMIAL=1
```

## VWALD

P.W. Goedhart, W.G. Buist &amp; B. Engel

Saves non-hierarchical Wald tests for fixed terms in a REML analysis

[contents](#) [previous](#) [next](#)

### Options

PRINT = <i>string token</i>	Whether to print the test statistics and associated probabilities and degrees of freedom ( <i>test</i> ); default <i>test</i>
SORT = <i>string token</i>	Whether to sort the results of the tests into ascending order according to the probabilities ( <i>yes, no</i> ); default <i>no</i>
PMETHOD = <i>string token</i>	Controls which distribution to use for calculating p values ( <i>chisquared, fdistribution</i> ); default <i>fdistribution</i>
WMETHOD = <i>string token</i>	Controls which Wald statistics are saved ( <i>add, drop</i> ); default <i>drop</i>

### Parameters

RESULTS = <i>pointer</i>	Pointer to save the tested terms and the test results
ADDLAST = <i>pointer</i>	Pointer to save results of the last model term in the FIXED formula as specified by means of VCOMPONENTS
DROPFIRST = <i>pointer</i>	Pointer to save results of the model term with the largest P value

### Description

A linear mixed model can be analysed by Restricted Maximum Likelihood (REML), as explained by e.g. Engel (1990). The REML directive implements REML, and significance (Wald) tests for fixed effects can be obtained with PRINT=waldtest. Two sets of Wald tests are then printed; these are named "Sequentially adding terms to fixed model" and "Dropping individual terms from full fixed model". This procedure can be used to save (and print) the latter Wald tests. Only tests for terms which are not marginal to a higher order interaction are produced.

The PMETHOD option controls how p-values are calculated for the significance tests. The significance test is always based on the Wald statistic. PMETHOD=chisquared calculates the p-value according to the chi-squared distribution. Alternatively PMETHOD=fdistribution employs the F statistic, which is the Wald statistic divided by its degrees of freedom. The p-value is then calculated by means of the F distribution with approximate denominator degrees of freedom as obtained by setting FMETHOD=auto of VKEEP. In case the denominator degrees of freedom is not available the chi-squared distribution is used. Note that in both cases the F statistic is printed. The denominator degrees of freedom is set to missing when the chi-squared distribution is used. The WMETHOD option controls whether the test statistics are for all terms which are added sequentially to the model, or only for those terms that can be dropped from the model. In the former case the principle of marginality might be violated.

The PRINT option controls the output of VWALD. For each term the F statistic (Fvalue) is printed along with its numerator (Ndf) and denominator (Ddf) degrees of freedom and the associated P value (Pvalue). For terms with a single degree of freedom the estimated effect and its standard error are also printed. The SORT option can be used to sort the results of the tests into ascending order according to the pvalue of the Wald tests. The RESULTS parameter can be used to save the tested terms and the test results. The ADDLAST and DROPFIRST parameters can be used to save results of specific terms of the FIXED model formula. ADDLAST and DROPFIRST can be used to implement model selection by means of forward selection, backward elimination or stepwise selection.

### Method

The fixed model formula is broken up into individual terms and for each term the Wald statistic is basically calculated as follows:

```
VKEEP      [FMETHOD=auto] TERMS=term ; \
           WALD=wald ; FSTATISTIC=fstat ; NDF=ndf ; DDF=ddf
IF (PMETHOD.EQS.'CHISQUARED') .OR. (ddf.EQ.C('*'))
  CALCULATE ddf = missing
```

```

      CALCULATE pvalue = CUCHI(wald ; ndf)
    ELSE
      CALCULATE pvalue = CUF(fstat ; ndf ; ddf)
    ENDIF

```

Note that only the F statistic is printed as the Wald statistic equals the F statistic times its (numerator) degrees of freedom. When the constant is omitted from the model it is included into the effects of the first term including a factor of the fixed model. The calculated statistic for this term can therefore be misleading and VWALD will print a warning message.

### Action with RESTRICT

Not relevant.

## WEAVEVECTORS

*L.C.P. Keizer & J.T.N.M. Thissen*

Weaves two sets of vectors into a new set according to the first vector of both sets

[contents](#) [previous](#) -

### Options

<code>SORT = string token</code>	Whether to sort the target vector (yes, no); default no
<code>DIRECTION = string token</code>	Order in which to sort the target vector (ascending, descending); default ascending

### Parameters

<code>FIRSTSET = pointers</code>	First set of vectors to interweave; must be set
<code>SECONDSET = pointers</code>	Second set of vectors to interweave; must be set
<code>COMBINATION = pointers</code>	To save the combined sets of vectors; must be set

### Description

Procedure WEAVEVECTORS can be used to weave two sets of vectors into a new set of vectors according to the first vector of both sets. WEAVEVECTORS is especially useful when combining two data sets with a common target vector. The two sets are specified by parameters FIRSTSET and SECONDSET. The type of the first vector in both sets must be the same, either a variate or a text. Each of the first vectors must have unique values. The weaving goes as follows: take all the elements of the first vector of FIRSTSET and add those elements of the first vector of SECONDSET not equal to any element of the first vector in FIRSTSET. The result of the weaving is a target vector according to which both sets of vectors are combined. The target vector is the first vector of the COMBINATION pointer with which the result must be saved. The other vectors of COMBINATION are then subsequently the other modified vectors of FIRSTSET and the other modified vectors of SECONDSET.

Option SORT can be used, in combination with the DIRECTION option, to sort the target vector in ascending or descending order. If SORT=no the elements of the target vector are the elements of the first vector in FIRSTSET supplemented by the elements of the first vector in SECONDSET not equal to the elements of the first vector in FIRSTSET.

### Method

The weaving is done with directive EQUATE and proper specifications of the options OLDFORMAT and NEWFORMAT.

### Action with RESTRICT

The vectors in FIRSTSET and SECONDSET must not be restricted.

### References

None.

### Procedures Used

None.

### Similar Procedures

MATCHTARGET extracts units of a set of vectors according to a target vector. JOIN joins or merges two sets of vectors together, based on the values of sets of classifying keys.
